
THE THIRD ANNUAL REPORT

OF THE

COMMISSIONER OF HEALTH

OF THE

COMMONWEALTH OF PENNSYLVANIA

1908

HARRISBURG:
C. E. AUGHINBAUGH, PRINTER TO THE STATE OF PENNSYLVANIA
1909.

TABLE OF CONTENTS.

LETTER OF TRANSMITTAL.

Commonwealth of Pennsylvania,
State Capitol Harrisburg,

December 31, 1909.

To His Excellency, Edwin S. Stuart, Governor of Pennsylvania:

Sir: In compliance with the requirements of Section 13 of the act "Creating a Department of Health and defining its duties and powers," approved the 27th day of April, A. D. 1905, I have the honor to submit to your Excellency my third annual report upon "the vital statistics and sanitary conditions and prospects of the State," covering the year ending December 31, 1908.

SAMUEL G. DIXON,
Commissioner of Health.

1—17—1908

THIRD ANNUAL REPORT

OF THE

COMMISSIONER OF HEALTH

OF THE

Commonwealth of Pennsylvania.

It is my sad duty to call your Excellency's attention to a vacancy existing on the Advisory Board of the Department, caused by the sudden death of Dr. Samuel T. Davis, while on a hunting trip in a remote valley in the mountains of Mexico. Dr. Davis was the only member of that Board who had served on the old State Board of Health, in the creation of which he took an active part, as a member of the Legislature, and of which he was President for many years. His large experience made him a valuable member of the Board and his genial qualities constituted him an acceptable associate.

The approaching completion of the Tuberculosis Sanatorium at Mt. Alto and consequent rapid increase of the number of patients rendered necessary an increase of the resident medical staff at that place. Dr. Fred C. Johnson, the Chief of the Division of Medical Inspection, was therefore transferred to the South Mountain Sana-

torium, becoming Medical Director, while Dr. A. M. Rothrock, the former Resident Physician, continued in service with the title of Vice Medical Director.

Dr. A. B. Moulton, former Assistant Medical Inspector, was promoted to the position of Chief Medical Inspector, and his desk was occupied by Dr. B. Franklin Royer, who for four and a half years was Chief Resident Physician to the Municipal Hospital of Philadelphia, thus enjoying unusual opportunities for becoming familiar with the diagnosis of communicable diseases. Dr. Royer's title is Associate Chief Medical Inspector.

The increasing claims upon the Tuberculosis Dispensaries have made it necessary to establish additional Dispensaries in many counties, and as it was often impossible for the County Medical Inspector in those Counties to take charge of two dispensaries, this necessitated the appointment of Physicians-in-Charge.

The Counties in which more than one dispensary is established with the names of the Physicians-in-Charge are:

County.	Town.	Physician-in-Charge.
Allegheny,	McKeesport,	Dr. D. P. Blose.
	Carnegie,	Dr. F. E. Herriott.
	Homestead,	Dr. A. P. Fogelman.
Beaver,	Beaver Falls,	Dr. Bruce Snodgrass.
Blair,	Tyrone,	Dr. W. S. Musser.
Bucks,	Bristol,	Dr. J. de B. Abbott.
Cambria,	Hastings,	Dr. D. S. Rice.
Carbon,	Lansford,	Dr. J. H. Young.
Center,	Philipsburg,	Dr. C. E. McGirk.
	Coatesville,	Dr. E. A. Graves.
	Phoenixville,	Dr. C. A. Yocum.
Clearfield,	DuBois,	Dr. R. R. Jordan.
Columbia,	Bloomsburg,	Dr. S. B. Arment.
Crawford,	Titusville,	Dr. J. M. Waide.
Cumberland,	W. Fairview,	Dr. Harvey Bashore.
Dauphin,	Lykens,	Dr. M. D. Lehr.
Erie,	Corry,	Dr. C. B. Kibler.
Fayette,	Connellsville,	Dr. T. B. Echard.
Jefferson,	Brookville,	Dr. J. A. Haven.
Lackawanna,	Carbondale,	Dr. W. J. Lowry.
Lancaster,	Columbia,	Dr. J. P. Kennedy.
Luzerne,	Hazleton,	Dr. W. C. Gayley.
	Pittston,	Dr. S. L. Underwood.
Montgomery,	Jenkintown,	Dr. W. B. Jamison.
	Pottstown,	Dr. T. E. Wills.
Northampton,	Bangor,	Dr. H. S. Sherrer.
	S. Bethlehem,	Dr. W. D. Chase.
Northumberland,	Mt. Carmel,	Dr. W. T. Williams.
	Milton,	Dr. R. B. Tule.
Philadelphia,	Phila. (Frankford),	Dr. Alfred Stengel.
Schuylkill,	Shenandoah,	Dr. H. M. Wasley.
	Tamaqua,	Dr. E. E. Shifferstein.
Susquehanna,	Susquehanna,	Dr. Sam'l Birdsall.
Tioga,	Wellsboro,	Dr. Penrose Houser.
Venango,	Franklin,	Dr. H. F. McDowell.
Washington,	Washington,	Dr. E. M. Hazlett.
Westmoreland,	Mt. Pleasant,	Dr. M. W. Horner.
	Monessen,	Dr. M. J. Cramer.
York,	Hanover,	Dr. J. H. Bittinger.

At many of the Dispensaries the number of the patients has been so great that it was absolutely impossible for one man to do the work with anything like justice to the patients. It has therefore become imperative to appoint assistants to the County Medical Inspectors and Physicians-in-Charge. These appointments have been as follows:

Name.	Place.
Dr. I. H. Alexander,	Pittsburg.
Dr. J. M. Long,	Pittsburg.
Dr. J. F. Edwards,	Pittsburg.
Dr. S. Hamilton,	Pittsburg.
Dr. C. J. McKee,	Pittsburg.
Dr. F. Stalzenbach,	Pittsburg.
Dr. C. W. Sample,	Pittsburg.
Dr. G. H. Boyd,	Pittsburg.
Dr. H. B. Stone,	Kittanning.
Dr. E. B. Miller,	Altoona.
Dr. T. M. Maxwell,	Butler.
Dr. J. McAneney,	Johnstown.
Dr. Thom,	Johnstown.
Dr. Jos. Cohen,	Berwick.
Dr. W. E. Hyskell,	Meadville.
Dr. R. Plank,	Carlisle.
Dr. J. W. Ellenberger,	Harrisburg.
Dr. C. R. Phillipps,	Harrisburg.
Dr. E. S. Haines (resigned),	Chester.
Dr. J. W. Wood,	Chester.
Dr. A. H. Roth,	Erie.
Dr. C. Falkowsky,	Scranton.
Dr. Jos. Wagner,	Scranton.
Dr. S. H. Heller,	Lancaster.
Dr. H. F. Myers,	Lancaster.
Dr. J. D. Tucker,	New Castle.
Dr. H. E. Maulfair,	Lebanon.
Dr. W. D. Kline,	Allentown.
Dr. F. C. Bausch,	Allentown.
Dr. J. W. Geist,	Wilkes-Barre.
Dr. S. Reichard,	Wilkes-Barre.
Dr. S. D. Wyckoff,	Wilkes-Barre.
Dr. G. W. Carr,	Wilkes-Barre.
Dr. J. A. Hilbert,	Wilkes-Barre.
Dr. G. R. Grosser,	Wilkes-Barre.
Dr. R. Wadhams,	Wilkes-Barre.
Dr. Walter Davis,	Wilkes-Barre.
Dr. G. H. McConnon,	Wilkes-Barre.
Dr. T. C. Zulick,	Easton.
Dr. W. P. Thompson,	Easton.
Dr. W. H. McIlkaney,	Easton.
Dr. J. E. Fretz,	Easton.
Dr. C. H. Malone,	Shamokin.
Dr. A. P. Francine,	Philadelphia.
Dr. W. G. Turnbull,	Philadelphia.
Dr. George Wood,	Philadelphia.
Dr. Fannie Davis,	Oil City.
Dr. Roland Jessup,	York.
Dr. B. F. Parker,	York.
Dr. J. H. Bennet,	York.
Dr. L. S. Weaver,	York.
Dr. H. D. Smyser,	York.
Dr. E. Meisenhelder,	York.
Dr. B. W. Shirey,	York.
Dr. L. M. Hartman,	York.
Dr. W. C. Smith,	York.

At the close of the year therefore the organization of the Department was as follows:

STATE CAPITOL, HARRISBURG.

Commissioner of Health, Samuel G. Dixon, M. D.

ADVISORY BOARD.

Adolph Koenig, M. D. Lee Masterson, C. E.
Leonard Pearson, M. D. Charles B. Penrose, M. D.
B. H. Warren, M. D.

Assistant to the Commissioner, Benjamin Lee, M. D.
Secretary to the Commissioner, Wilbur Morse.
Stenographers, Miss Ivy E. Huber.
Miss Mary Stephen Mark.
Messenger, Edward F. Eisely.
Janitor, John B. Sample.

MEDICAL DIVISION.

Chief Medical Inspector, Arthur B. Moulton, M. D.
Associate Chief Medical Inspector, B. Franklin Royer, M. D.
Stenographers, Miss Fannie A. Houseknecht.
Miss Dorothy Sterline.
Connected with this Division are 723 Township Health Officers.

COUNTY MEDICAL INSPECTORS.

County.	Inspector.	Post Office.
Adams,	John R. Dickson,	Gettysburg.
Allegheny,	S. M. Rinehart,	Northside, Pittsburg.
Armstrong,	T. N. McKee,	Kittanning.
Beaver,	E. S. H. McCauley,	Beaver,
Bedford,	D. de la M. Hill,	Everett.
Berks,	Isreal Cleaver,	Reading.
Blair,	Wm. M. Findley,	Altoona.
Bradford,	S. M. Woodburn,	Towanda.
Bucks,	I. S. Plymire,	Doylestown.
Butler,	H. D. Heckenberry,	West Sunbury.
Cambria,	Wm. E. Matthews,	Johnstown.
Cameron,	H. S. Falk,	Emporium.
Carbon,	John K. Henry,	Mauch Chunk.
Centre,	George F. Harris,	Bellefonte.
Chester,	Joseph Scattergood,	West Chester.
Clarion,	J. T. Riner,	Clarion.
Clearfield,	S. C. Stewart,	Clearfield.
Clinton,	R. B. Watson,	Lock Haven.
Columbia,	S. B. Ament,	Bloomsburg.
Crawford,	J. R. Roberts,	Meadville.
Cumberland,	Harvey B. Bashore,	West Fairview.
Dauphin,	Paul A. Hartman,	Harrisburg.
Delaware,	Robert S. Maison,	Chester.
Elk,	W. L. Williams,	Ridgway.
Erie,	J. W. Wright,	Erie.
Fayette,	O. R. Altman,	Uniontown.
Forest,	T. J. Bovard,	Tionesta.
Franklin,	H. X. Bonbrake,	Chambersburg.
Fulton,	J. W. Mosser,	McConnellsburg.

COUNTY MEDICAL INSPECTORS.—Continued.

County.	Inspector.	Post Office.
Greene,	John T. Iams,	Waynesburg.
Huntingdon,	W. C. Frontz,	Huntingdon.
Indiana,	N. F. Ehrenfeld,	Indiana.
Jefferson,	J. E. Grube,	Punxsutawney.
Juniata,	William H. Banks,	Mifflintown.
Lackawanna,	J. C. Reifsynder,	Scranton.
Lancaster,	J. L. Mowrey,	Lancaster.
Lawrence,	J. D. Moore,	New Castle.
Lehigh,	Morris F. Cawley,	Allentown.
Lebanon,	A. J. Riegel,	Lebanon.
Luzerne,	C. H. Miner,	Wilkes-Barre.
Lycoming,	Charles H. Youngman,	Williamsport.
McKean,	W. C. Hogan,	Bradford.
Mercer,	P. P. Fisher,	Sharon.
Mifflin,	C. H. Brisbin,	Lewistown.
Monroe,	W. E. Gregory,	Stroudsburg.
Montgomery,	H. H. Whitcomb,	Norristown.
Montour,	G. A. Shock,	Danville.
Northampton,	E. M. Green,	Easton.
Northumberland,	R. H. Simmons,	Shamokin.
Perry,	A. R. Johnston,	New Bloomfield.
Pike,	Wm. B. Kenworthy,	Milford.
Potter,	E. H. Ashcraft,	Coudersport.
Schuylkill,	L. T. Kennedy,	Pottsville.
Snyder,	F. J. Wagenseller,	Selinsgrove.
Somerset,	Charles P. Large,	Meyersdale.
Sullivan,	J. L. Christian,	Lopez.
Susquehanna,	H. B. Lathrop,	Springville.
Tioga,	S. P. Hakes,	Tioga.
Union,	C. H. Dimm,	Mifflinburg.
Venango,	J. P. Strayer,	Oil City.
Warren,	M. V. Ball,	Warren.
Washington,	C. B. Wood,	Monongahela.
Wayne,	H. B. Ely,	Honesdale.
Westmoreland,	I. M. Portser,	Greensburg.
Wyoming,	E. E. Bidleman,	Tunkhannock.
York,	J. S. Miller,	York.

RAILROAD MEDICAL INSPECTORS.

(Commissioned by the Commissioner of Health but not paid by the State.)

PENNSYLVANIA RAILROAD COMPANY.

Dr. S. W. Latta, Chief Medical Inspector, Philadelphia.

Dr. D. W. Nead, Philadelphia.
Dr. E. C. Town, Philadelphia.
Dr. J. L. Wright, Columbia.
Dr. S. M. Crawford, Harrisburg.
Dr. C. J. Roberts, Williamsport.
Dr. S. A. Bonnafon, Erie.
Dr. H. W. Pownall, Tyrone.
Dr. C. F. Hough, Cresson.
Dr. D. N. Easter, Youngwood.
Dr. J. B. Hileman, Pitcairn.
Dr. W. B. Reynolds, Olean.
Dr. I. H. Boyd, Philadelphia.
Dr. J. L. Bower, Reading.
Dr. W. T. Bishop, York.
Dr. A. T. Poffenberger, Sunbury.
Dr. J. B. Lincoln, Renovo.
Dr. R. H. Moore, Huntingdon.
Dr. W. B. Diefenderfer, Altoona.
Dr. C. W. Banks, Derry.
Dr. W. K. T. Sann, Pittsburg.
Dr. J. C. Lemmer, Oil City.
Dr. H. E. Westhaeffer, Monongahela City.

PHILADELPHIA AND READING RAILWAY COMPANY.

Dr. Caspar Morris, Chief Medical Inspector, Philadelphia.

Dr. Frederick E. Briester, Phila.
Dr. Norris S. McDowell, Phila.
Dr. J. Henry Orff, Reading.
Dr. Albert F. Bronson, Tamaqua.
Dr. Francis S. Ferris, Phila.
Dr. Charles F. Detweiler, Reading.
Dr. Thomas F. Heebner, Pottsville.
Dr. Wm. R. Brothers, Harrisburg.

BALTIMORE AND OHIO RAILROAD COMPANY.

Dr. John L. Burkholder, New Castle Junction.

Dr. I. D. Chaney, Connellsville.
Dr. W. A. Funk, Pittsburg.
Dr. M. H. Koehler, Connellsville.
Dr. W. B. Rogers, Pittsburg.
Dr. H. F. Atkinson, Connellsville.
Dr. E. M. Baker, Valencia.
Dr. J. A. Batton, Uniontown.
Dr. H. J. Bell, Dawson.
Dr. F. C. Blessing, Pittsburg.
Dr. W. J. Bryson, Pittsburg.
Dr. M. C. Cameron, Pittsburg.
Dr. C. L. Clover, Knox.
Dr. Arthur E. Crow, Uniontown.
Dr. C. L. DeWolfe, Chicora.
Dr. E. L. Dickey, St. Petersburg.
Dr. E. A. Donnan, New Castle.
Dr. John Foster, New Castle.
Dr. E. A. Fleetwood, Pittsburg.
Dr. G. R. Gaver, Pittsburg.
Dr. A. L. Porter, Philadelphia.
Dr. D. E. Stephen, New Castle Junction.
Dr. W. J. Bailey, Connellsville.
Dr. H. Baker, Connellsville.
Dr. J. E. S. Bell, Pittsburg.
Dr. J. B. Black, Cristy Park.
Dr. Robt. W. Brace, Philadelphia.
Dr. L. N. Burchinal, Point Marion.
Dr. W. H. Cameron, Pittsburg.
Dr. John B. Critchfield, Ralphton.
Dr. C. L. Curll, Pittsburg.
Dr. W. L. DeWolfe, Butler.
Dr. W. F. Donaldson, Pittsburg.
Dr. F. H. Evans, Chester.
Dr. W. S. Foster, Pittsburg.
Dr. J. S. Garman, Berlin.
Dr. W. D. Haight, Johnstown.
Dr. James M. Hess, Marienville.
Dr. A. M. Hoover, Parker's Landing.
Dr. T. L. Kane, Kane.
Dr. Bruce Lichty, Meyersdale.
Dr. A. K. Lyon, Allegheny.
Dr. H. I. Marsden, Somerset.
Dr. G. B. Masters, Rockwood.
Dr. W. T. Messmore, Smithfield.
Dr. E. S. Montgomery, Pittsburg.
Dr. E. J. Morris, Philadelphia.
Dr. William F. Morrison, Phila.
Dr. W. S. Mountain, Confluence.
Dr. W. D. O'Brien, Pittsburg.
Dr. Benj. W. Phillips, Tylersburg.
Dr. R. T. Pollard, Garrett.
Dr. S. E. Ralston, Zelienople.
Dr. F. P. Righter, Markleton.
Dr. J. Q. Robinson, West Newton.
Dr. W. T. Rowe, Meyersdale.
Dr. W. A. Shannon, Ellwood City.
Dr. M. B. Shupe, Connellsville.
Dr. J. N. Sprowls, Claysville.
Dr. C. J. Styber, Allegheny.
Dr. B. Thompson, Landenburg.
Dr. J. N. Timmons, W. Alexander.
Dr. W. E. Walker, McKeesport.
Dr. W. A. Garman, Berlin.
Dr. H. R. Hardtmayer, Allegheny.
Dr. Hiram Miller, Chester.
Dr. E. O. Kane, Kane.

Dr. A. M. Lichty, Elk Lick.
Dr. D. C. Lindley, New Castle.
Dr. F. L. Marsh, Mt. Pleasant.
Dr. R. S. McKee, New Haven.
Dr. H. A. Miller, Pittsburg.
Dr. R. H. Pillow, Butler.
Dr. J. H. Price, Allison Park.
Dr. D. T. Rees, Hyndman.
Dr. W. F. Robeson, Pittsburg.
Dr. C. C. Ross, Clarion.
Dr. J. H. Shannon, Washington.
Dr. J. C. Sheridan, Johnstown.
Dr. A. R. Shuster, Finleyville.
Dr. W. S. Stewart, Braddock.
Dr. V. F. Thomas, Evans City.
Dr. W. R. Thompson, Washington.
Dr. A. W. Urmson, New Castle.
Dr. W. W. Weaver, Philadelphia.
Dr. F. H. Weidmann, Confluence.
Dr. C. H. Wilson, Glenwood.
Dr. W. M. Woodward, McKeesport.
Dr. T. H. White, Connellsville.
Dr. H. R. Wilson, Callery.
Dr. H. A. Zimmerman, Holsopple.

SUB-DIVISION, SANATORIA AND DISPENSARIES FOR THE TREATMENT OF TUBERCULOSIS.

Medical Director, Mt. Alto Tuberculosis Sanatorium, Fred C. Johnson, M. D.
Chief Resident Physician, A. M. Rothrock, M. D.
Medical Inspector of Dispensaries, Thomas H. A. Stites, M. D.
Stenographers, Miss Olive E. Jamison.
Miss Nellie M. Tittle.
Miss Josephine Hill.

SUB-DIVISION SPECIAL MEDICAL INSPECTION.

Special Medical Inspector, John A. Bouse, M. D.
Stenographer, Miss Mary E. Sandoe.

COUNTY DISPENSARIES FOR TUBERCULOSIS.

County.	Location.	Chief (Assisted by Medical Staff and Nurses).
Adams,	Gettysburg,	J. R. Dickson, M. D.
Allegheny,	Pittsburg,	S. M. Rinehart, M. D.
		J. F. Edwards, M. D.
Armstrong,	Kittanning,	T. N. McKee, M. D.
Beaver,	Rochester,	E. S. H. McCauley, M. D.
Bedford,	Everett,	W. de la M. Hill, M. D.
Berks,	Reading,	Israel Cleaver, M. D.
Blair,	Altoona,	Joseph D. Findley, M. D.
Bradford,	Towanda,	S. M. Woodburn, M. D.
Bucks,	Doylestown,	I. S. Plumire, M. D.
Butler,	Butler,	H. D. Hockenberry, M. D.
Cambria,	Johnstown,	William E. Matthews, M. D.
Cameron,	Emporium,	H. S. Falk, M. D.
Carbon,	Mauch Chunk,	J. K. Henry, M. D.
Centre,	Bellefonte,	Geo. F. Harris, M. D.

COUNTY DISPENSARIES FOR TUBERCULOSIS.—Continued.

County.	Location.	Chief (Assisted by Medical Staff and Nurses).

York,	York,	J. S. Miller, M. D.

CENTRAL BUREAU OF VITAL STATISTICS.

State Registrar, Wilmer R. Batt, M. D.

Chief Clerk, Herbert B. Nelson.

Clerks, Elmer W. Ehler.
H. E. Fox.

Stenographers, Miss Erma R. Longenecker.
Miss Lila H. Connelly.
Miss Anna Madeburg.
Miss Margaret D. Prescott.

Morbidity Statistics Sub-Division in charge of Wilmer R. Batt, M. D.
Clerks, Mrs. Edith L. M. Huber.
Miss Katharine Irene McCauley.
Miss Martha E. McGranagan.

Marriage Statistics Sub-Division in charge of Wilmer R. Batt, M. D.
Clerks, Miss Emilie Charters.
Miss Teresa Neupert.
Miss Josephine Snavely.
Miss Martha Ziegler.

In this Department are employed 972 Local Registrars, each with a Deputy, and 214 Sub-registrars.

DIVISION OF SANITARY ENGINEERING.

Chief Engineer, F. Herbert Snow, C. E.

Principal Assistant Engineer in charge of General Office Work, Walter S. Hanna.

Principal Assistant Engineer in charge of Special Investigation, Charles H. Cummings.

Principal Assistant Engineer in charge of design and construction, Thomas Fleming.

Assistant Engineer, William H. Ennis.

Engineer and Draftsman, John M. Mahon, Jr.

Chief Draftsman, James L. W. Gibbs.

Engineering Inspector, H. A. Otto.

Engineering Inspector, F. L. Gardner.

Transitmen, Chester A. Eckbert.
C. R. Forbes.

Rodmen, Edgar R. Barnes.
Ivan M. Glace.

Tracers, J. W. German, Jr.
Max Matthes.
F. M. Sourbier, Jr.

Chief Clerk in charge of nuisance complaints, Daniel V. Ness.

Chief Clerk in charge of local health officer work, B. C. Dickinson.

Clerk, Mrs. Ellen Johnston.

Stenographers, Miss M. Irene Cuenot.
Miss M. Louise Eckels.
Miss Jane Gilbert.
Miss M. Ethel Hurst.
Miss Mary E. Russell.
Mrs. Mary K. Sourbier.

Chief Sanitary Inspector, M. K. Ely.

Field Officers in charge, James M. Clark.
David H. Coleman.
John J. Considine.
J. B. Nightingale.
John W. Pinkham.
William R. Teats.
Special Field Inspectors, Wilson W. Ritter.
Daniel Zellers.
Ira F. Ziegler.
Field Officers, Henry Andrews.
W. R. Claypool.
John W. Downes.
Richard F. Einstein.
Morris Z. Frederick.
Howard M. Haines.
Thomas Hickey.
Warren S. Hood.
J. Alfred Judge.
H. S. Kauffman.
W. F. Lerch.
Chas. T. Maclay.
William P. Miller.
Thomas R. Nicholson.
Otto F. Nickel.
W. W. Reno.
Roy Souder.
Chas. P. Spelker.
H. C. Weirick.

LABORATORIES AND EXPERIMENTAL STATION.

Director of Pathology ,Allen J. Smith, M. D., University of Pennsylvania, Philadelphia.
Chief of the Laboratories, Herbert Fox, M. D.
Bacteriologist, Damaso Rivas.
Assistant Bacteriologist, James B. Rucker, M. D.
Assistant, Miss Lucy H. Irwin.
Stenographer, Miss Helen M. O'Donnell.
Laboratory Diener, John R. Taylor.
Animal Diener, Leon J. Harris.

DIVISION OF DISTRIBUTION OF BIOLOGICAL PRODUCTS.

Chief of Division, Henry W. Pierson.
Stenographer, Mrs. Lucy A. Thompson.
Clerk, Miss Mabel E. Thorn.
There are 532 Antitoxin Distributors throughout the State.

DVISION OF ACCOUNTING AND PURCHASING.

Office 1900 Race Street, Philadelphia.

Accounting and Purchasing Agent, E. I. Simpson.
Bookkeepers, Miss Agnes E. Bean.
Miss Mary L. Thompson.
Stenographers, Miss Minnie A. Light.
Miss Mary G. Lynch.

DIVISION OF SUPPLIES.

Superintendent, Charles Hartzell.
Clerks, Miss Susan J. Riegel.
Miss Rosie E. VanHorn.
Miss Maud E. VanOrmer.

ESTABLISHMENT OF NEW BOARDS.

Allusion was made in the last annual report to the absence of or defective organization of the health boards in many boroughs and first-class townships and to the serious handicap which this condition entailed in perfecting the sanitary organization of the State. The action then taken in appointing a special Medical Inspector to inquire into this condition both by correspondence and by personal visitation has been amply justified. Ignorance of the requirements of the law and the methods of sanitary procedure together with the entirely inadequate appropriations made by councils for this purpose were found to be the main causes of our backwardness in these matters. The personal interest taken by the Department in the sanitary welfare of the smaller towns is, however, awakening a gratifying response. During the year, seventy-two new boards were organized in fifty-two separate counties. Many of these were in towns remote from centres of population and in the mountainous districts of the State. In the month of September the report of this officer showed that the number of boroughs in the State was 882, of which 718 had organized boards. Of these 449 had filed reports with the Department. This left 173 still unprovided.

The number of counties in which every borough organized was 18. The number in which five or less than five boroughs were unorganized was 38, and the number in which more than five were unorganized was 11. The circular of the Department on room disinfection was warmly welcomed, on account of its clearness and definiteness, and was adopted by many of the old boards as well as those just organized. A detailed report of this work will be found under the Operations of the Divisions.

THE PREVENTION OF BLINDNESS.

The American Medical Association at its last annual meeting authorized the issue of the Report of the Committee on Ophthalmia Neonatorum, which called attention to the fact that a very large percentage of the cases of blindness which the State is called upon to support is caused by that disease, which is an easily preventable one, and urged the necessity for concerted action on the part of the medical profession in all the States of the Union to curtail this serious evil. That this appeal is timely is sufficiently indicated by a recent report of the Pennsylvania School for the Blind, which shows that in the past eight years more than one-third of the persons admitted to that institution have owed their affliction to this cause.

It was therefore thought desirable to revive and put into effect a law which has for many years lain dormant on our statute book, which reads as follows:

AN ACT.

For the prevention of blindness, imposing a duty upon all midwives, nurses or other persons having the care of infants, and also upon the health officer, and fixing a penalty for neglect thereof.

Whereas, Statistics compiled in this country and Europe demonstrate that fully twenty-five per centum of the blind owe their affliction to an inflammation of the conjunctiva appearing a few days after birth;

And Whereas, Experience has proved that the inflammation can be cured and the eyesight saved in the majority of cases if treatment be instituted at an early stage of the disease;

And Whereas, Destruction of the eyes and blindness are usually the result of delay of treatment.

Section 1. Be it enacted, etc., That should one or both eyes of an infant become inflamed or swollen or reddened at any time within two weeks after birth, it shall be the duty of the midwife or nurse, or other person having the care of such infant, to report in writing, within six hours after the discovery thereof, to the health officer or legally qualified practitioner of the city, town or district in which the mother of the child resides, the fact that such inflammation or swelling or redness exists.

Section 2. That it shall be the duty of said health officer, immediately upon receipt of said written report, to notify the parents or the person having charge of said infant of the danger to the eye or eyes of said infant by reason of said condition from neglect of proper treatment of the same, and he shall also enclose to them directions for the proper treatment thereof.

Section 3. Every health officer shall furnish a copy of this act to each person who is known to him to act as midwife or nurse in the city or town for which such health officer is appointed, and the Secretary of State shall cause a sufficient number of copies of this act to be printed and supply the same to such health officers on application.

Section 4. Any failure to comply with the provisions of this act shall be punishable by fine not to exceed two hundred dollars, or imprisonment not to exceed thirty days, or both.

APPROVED.—The 26th day of June A. D. 1895.

DANIEL H. HASTINGS.

Copies of the above law were distributed to all physicians and midwives throughout the State, together with letters of explanation and instruction.

The following instructions were sent to Health Officers of the Department of Health:

"In order to carry out the provisions of the above law, it becomes your duty to acquaint yourself with the names and adddesses of all midwives and nurses residing or practicing in your district and to place a copy of the law in the hands of each, instructing her as to its requirements.

"Immediately on receiving notification from a midwife or nurse of the occurrence of a case of red or swollen eyes in a young infant, you will inform the attending physician of the fact, and will place in the hands of the midwife or nurse the accompanying instructions, explaining that she is to follow them ONLY UNTIL A PHYSICIAN ARRIVES to take charge of the case. If no physician has been employed you will urge upon the family the necessity for obtaining one, as otherwise the child may become permanently blind."

"Instructions to Nurses and Midwives for Treating Inflamed Eyes in Newborn Infants UNTIL THE PHYSICIAN ARRIVES:

To one pint of boiled water add two teaspoonfuls of boric acid and half a teaspoonful of table salt, and keep covered in a jar which has been boiled. With a perfectly clean cloth or a wad of absorbent cotton bathe the lids with this solution, and drop a few drops in the eye three times a day."

Of course the intention of the law is that the physician shall treat the eye with a salt of silver, or some equally efficacious agent, but deeming it inexpedient to entrust the use of so strong an application to the unskilled hands of a nurse or midwife, we suggested the use of the above harmless but efficacious detergent until the services of a physician could be secured. It is hoped by the enforcement of this law to put an end to a fertile cause of misery and disability and save the state from a serious burden. In this connection the following communications were addressed to County Medical Inspectors and local boards of health:

Dr. ————,

County Medical Inspector.

Dear Sir: Your attention is called to the enclosed copy of the law of June 26, 1895, P. L. 373, designed to prevent blindness in a large and increasing number of cases in this state.

The statistics of the Pennsylvania School for the Blind show that the average annual percentage of cases of blindness received in that

school for the past eight years directly attributable to Ophthalmia Neonatorum, has been 33. All of this misery and disability is preventable.

As you will observe the onus of the enforcement of the law rests upon the health officers and midwives and nurses. I trust, however, that you will lose no opportunity to use your influence to aid them in the discharge of this important duty.

Yours very truly,

SAMUEL G. DIXON,
Commissioner.

To the Secretary of Board of Health of

_____

_____

Dear Sir: Allow me to call your attention to the enclosed copy of the Act of June 26, 1895, P. L. 373, having for its object the prevention of blindness. If its provisions are carried out there is reason to hope that one-third of the cases of that sad affliction, which so greatly diminishes the productive value of the individual and too often renders him a burden on society, may be prevented.

This Department is already taking steps through its County Medical Inspectors and Health Officers to enforce the law in the rural districts. I venture to express the hope that your Board will appreciate the serious importance of the question and adopt such measures as will lead to its early enforcement in the municipality under your jurisdiction.

Yours very truly,

SAMUEL G. DIXON,
Commissioner.

THE STATE'S OFFICIAL CAMPAIGN AGAINST TUBERCULOSIS.

The opening of the year found the campaign of the Department against Tuberculosis fairly inaugurated. I was able to report the Dispensary system as thoroughly organized, seventy-two dispensaries fully officered and equipped being in active operation and four hundred and thirty-five applicants having received attention.

Eighty-three have been opened during the year, making the present number one hundred and five, and a further extension of the system is in contemplation. Under the report of the Medical Inspector of Dispensaries will be found a list of the location and a statement of the equipment of the dispensaries and of the method of dispensary work, and other details of interest.

It was felt that in addition to notices in the public press it was desirable to give the fact of the inauguration of this movement the

widest publicity in those quarters where it would be most likely to reach the sufferers. The following letters were therefore addressed to different classes of individuals, private and well as official:

To the Secretary of each local Board of Health.

"Dear Sir: It is desirable that you and the members of your Board should have accurate information with regard to the campaign which this Department is inaugurating against that deadly foe of human life, Pulmonary Tuberculosis, generaally known as Consumption of the Lungs.

"By your own personal investigations, as well as through your Health Officer, you become acquainted with the health conditions of every family in your town. You are informed through your system of vital statistics of every death from this disease that occurs, and you have learned that it is a communicable disease.

I therefore earnestly request you to make use of the facts which you thus officially obtain to disseminate to all whom it may especially concern a knowledge of the fact that the State Department of Health has opened a Tuberculosis Dispensary at ———— under the care of Dr. ————, County Medical Inspector, at which competent medical advice will be given and milk and eggs, the principal food of consumptives, will be furnished free of expense to indigent cases as well as such medicine as may be necessary.

In order to secure speedy recovery, cases should apply in the earliest stage of the disease.

Trusting that we shall have your earnest support in the contest against this inveterate enemy of the human race,

I am, Yours very truly,

Commissioner."

To the Secretary of each County Medical Society.

"Dear Doctor: Your Society is of course deeply interested in the wave of enthusiasm which is spreading all over our Country in a combined effort to check the ravages of Tuberculosis Pulmonalis. I feel sure, therefore, that the State Department of Health will have the active cooperation of your Society and of every member of the same in its endeavor to put our own State in the fore front of this important movement. In addition to the Sanatoria which the Legislature has authorized we are establishing a Tuberculosis Dispensary in each County of the State. In your own County it is located at ———— and will be under the charge of Dr. ————, County Medical Inspector.

Our object will be to place reliable medical advise within the reach of those whose means are so limited as to make it impossible for them to consult an expert or go to a pay Sanatorium.

To such persons as it seems necessary we shall also furnish milk and eggs and such medicines as seem to be essential free of cost.

Recent experience, as you are well aware, renders it of the utmost importance that the treatment of these cases should be begun at the earliest possible moment before the bacillus has produced much destruction of the lung tissue.

You are in a position to see and recognize suspicious cases long before the patient or the patient's friends suspect the presence of the organism.

I have most earnestly to request that whenever in your practice you meet a case that you feel to be needing and deserving State aid, you will lose no time in giving the necessary information, which may in a large proportion of cases lead to an arrest of the disease and the removal of a menace to the community.

Believe me, dear Doctor, Yours very truly,

Commissioner."

To each Township Health Officer.

"Dear Sir: The Department of Health desires to avail itself of your services in carrying on its campaign against Pulmonary Tuberculosis or Consumption of the Lungs. In order to reduce the prevalence and mortality of this most deadly of all diseases, we are establishing a Tuberculosis Dispensary in each County in the State, at which indigent persons threatened with or suffering from this disease can not only receive competent medical advice, but also food in the shape of milk and eggs and medicine, if needed.

Your duties give you an intimate knowledge of the conditions of life and pecuniary circumstances of the population of your district. You will be likely to learn of consumptives or of persons in failing health, and you will therefore enjoy an opportunity of advising such persons of the hope of recovery thus held out to them.

You are, therefore, instructed, in your visits throughout your district, to lose no chance of spreading this information as generally as possible and especially in families where you have reason to think that it is needed.

The dispensary of your County is located at ————, and the physician is Dr. ————, County Medical Inspector.

Yours truly,

Commissioner."

To the Secretary of Womens Clubs and Aid Associations, through clergymen:

"Will the pastor kindly see that this letter is placed in the hands of the Secretary of the Ladies' Aid Society or similar organization of the church and make such public announcement of the dispensary work from his pulpit as he may think best?

"Dear Madam: The Department of Health of the Commonwealth of Pennsylvania is desirous of obtaining the co-operation of yourself and the members of your association in its great fight against Tuberculosis of the Lungs, usually known as Consumption. It is now establishing in each county in the State a dispensary for the treatment of indigent persons suffering from this disease, a disease which is responsible for the deaths of a larger number of our people than any other. In your own county the dispensary is located at ———— and the County Medical Inspector who has charge of it is Dr. ————.

Any persons who suspect that their lungs are becoming affected and whose means do not permit them to go to a private sanatorium or expert, can, on applying at the dispensary on the advertised days, obtain a reliable opinion as to whether or not they have the disease in its early stage If they prove to need the special care here given they will receive exact instructions as to their diet and mode of living, and in cases where it seems desirable and practicable, they will be furnished the milk and eggs, which should constitute the greater part of their food, free of expense. Medicines, if needed, will also be furnished free.

Patients will, of course, be treated in any stage of the disease, but so far as the work of these dispensaries is to be curative, it is a matter of the utmost importance that cases should be seen as early as possible. It is here especially that the knowledge which your members possess of those needing aid can be of the greatest possible assistance. The patients themselves will be missionaries and educators in their own family and circle of acquaintances, disseminating the knowledge of the precautions which are absolutely essential for the protection of those around them from acquiring the disease.

"Nurses will also visit the homes of the patients in order to make sure that the instructions of the physician are faithfully carried out as well as to detect unsanitary conditions which might retard the patient's recovery. Trusting that you and your public-spirited associates will appreciate the field for usefulness thus opened and lend us your valuable assistance in this most important effort, in which to insure success, the whole people must join, I am Yours very truly,

SAMUEL G. DIXON,
Commissioner."

To employers of Labor.

"Dear Sir: As an employer of large numbers of operatives it is a matter of considerable importance to you that a high standard of health should be maintained among these whose daily labor contributes to the success of your enterprise. The experience of our Department will probably be corroborated by your own that Pulmonary Tuberculosis or Consumption of the Lungs is one of the most constant and serious obstacles to the steady prosecution of labor, striking down its victims, as it does, just at the time of life when their services are most valuable. I feel sure, therefore, that the State Department of Health will receive your ready co-operation in the effort which it is making to restrict the spread of this most serious of all infections.

The plan which this Department is developing is, in addition to the forest sanatoria authorized by law, to establish a Tuberculosis Dispensary in every County in the State, where sufferers from this deadly disease whose pecuniary means are limited, may obtain competent medical advice, food in the shape of milk and eggs, and, if necessary, medicine, free of expense.

The instructions which they will receive as to the precautions necessary to be taken to prevent them from transmitting the disease to other members of their families will be conveyed by them to the others and thus becomes a means of education to the entire community. In this way it is hoped to soon diminish this terrible leak in the productive resources of the country.

Allow me to suggest that it might be a remunerative scheme for you to institute a systematic Medical Inspection of your employees in order to detect the disease in its earliest stage when it is capable of cure, and to advise all suspicious cases to apply to the State County Dispensary for advice.

The Dispensary for ——— County is located at ..... It is in charge of ——— and is open

Yours very truly,
Commissioner."

It was owing to this effort in part as well as to the kindly and universal aid of the newspapers of the State that patients began to flock to the Dispensaries as soon as they were opened.

The total number applying at the Dispensaries during the year was 8699. The number remaining under treatment at the end of the year was 5204. The number in whom the disease was arrested was 105, and of those who left improved 1041. There were 500 deaths and 1249 applicants who paid only a single visit. The total number of visits at the dispensaries was 47,318, and the number of visits to patients at their homes by the nurses was 33,305. The number of quarts of milk dispensed was 385,818, and the number of dozen of eggs 54,403.

THE SOUTH MOUNTAIN SANATORIUM.

The work in preparation of the Sanatorium near Mont Alto in Franklin County was then described as well advanced and the temporary accommodation of a large number of incipient cases in new tents, manufactured for the purpose, under the direction of the Adjutant General was reported. Although the winter was a somewhat severe one, as the supply of blankets of good quality was adequate, there were few complaints of the cold, and not a single case of Penumonia developed. During the year the cottages then in process of erection have been completed to the number of forty-one and have proved to be entirely satisfactory. These afforded accommodations for 328 patients.

The advantage of the cottage system over that of the huge and costly hospital, with its magnificent architectural display and its large, crowded wards, is daily impressing itself on the minds of those in charge. Apart from the more complete ventilation thus secured, during the hours of sleep, the necessity of going into the open air for meals, and for visiting the bath and toilet houses, is of the greatest importance, as it overcome the inevitable tendency of patients to remain unnecessarily in bed, without the exercise of compulsion on the part of the physicians or other officers, which is always resented.

It is undoubtedly theoretically possible to restore an incipient consumptive to health in a city or near the sea level, but there is also practically no room for doubt that a moderate altitude, remote from the contaminating influences of the city, ensures a purity of atmosphere and equability of temperature which greatly hasten and facilitate the cure. Add to this an environment of balsamic forests through which the outside air is, so to speak, filtered and which serve to check violent meteorological commotions, and you have all the conditions usually sought after for a tuberculosis sanatorium at home or abroad.

Such are the natural conditions which prevail at South Mountain. A copious supply of pure water, adequate modern drainage and sewerage facilitates, with a disposal plant, good roads and paths, and a careful selection of sites for the camps have so enhanced these natural advantages, as to have led an enthusiastic visitor to entitle the settlement "The Hillside City of Hope."

Detailed descriptions of the cottages, pavilions and other buildings in the camp will be found in the Catalogue of the Exhibit of the Department at the International Tuberculosis Exhibition under the head of Operations of the Divisions.

The Representation of the Department at the International Congress on Tuberculosis at Washington, D. C.

Early in the year the following communication was received from the Governor of the State, with the request that an exhibit for this purpose, adequate to the importance of the Commonwealth and the occasion, should be prepared and forwarded to Washington.

TREASURY DEPARTMENT,
Washington, December 26, 1907.

Sir: The prevention of tuberculosis is engaging the increasing attention of public health authorities and philanthropists throughout the world. There is certainly no more important public health question demanding the activities of sanitary officers at the present time, and it is desirable that our people generally recognize its importance and enlist in the campaign against tuberculosis.

The diffusion of knowledge with respect to the disease is no doubt one of the most important measures that can be instituted by public health officials. With the view to this end, an International Congress on Tuberculosis will be held in Washington, D. C., September 21 to October 12, 1908. At this Congress all phases of the problem will be considered, a number of eminent specialists from abroad having signified their intention to participate in the deliberations.

Section VI will be devoted to the National, State and Municipal control of the disease, and it is urged that all public health officials attend its sessions, participate in the benefits to be derived from discussions of the governmental responsibilities and activities, and as a result be better prepared to assist in a systematic campaign aginst the disease throughout the country.

Respectfully,
WALTER WYMAN,
Surgeon-General.

By request of Surgeon-General Wyman I accepted the appointment of Vice-President of the Section referred to, of which he was himself the President. As Chairman of the Pennsylvania State Committee of the Congress, I shared in the preparation of the exhibits of the various voluntary organizations for the prevention of

tuberculosis throughout the State in addition to devising and arranging that of the Department. The State Registrar of Vital Statistics was deputed to supervise the transportation and installation of the latter. A descriptive catalogue of the Exhibit in pamphlet form, 31 pp. octavo, was distributed to visitors. This will be found later in the report.

Several members of the medical staff of the Department were present during the congress, explaining the exhibits in detail and giving lectures. Personally attending and presiding over the Section referred to, I read a paper, entitled "The Governmental Control of Tuberculosis Patients in Pennsylvania." Further reference to this congress will be made later as well as to the Seventh International Conference held at Philadelphia in September, where also I read a paper. These occasions assembled scientific students of the problems of tuberculosis from all parts of the world and undoubtedly gave a great impulse to the popular awakening on this question which the last few years have witnessed. It is proposed to install the Exhibit of the Department in the State Capitol for the information of the members of the Legislature and the citizens of Harrisburg during the coming Winter, and, after the adjournment of that body, to despatch it on a tour of instruction through the State, accompanied by a corps of carefully selected demonstrators and lecturers.

MORBIDITY REPORTS.

In a State where the reporting of disease has been to a great extent neglected, and in which indeed by many of the population the attempt to take a census has been violently opposed on religious grounds, it could not reasonably be expected that the first efforts to collect such figures would be in the least degree successful. In regard to mortality returns, the case is quite different. The necessity for burial affords a lever which can be worked with an approach to certainty. The number of deaths which fail of being reported is extremely small. But in illness there are elements of uncertainty apart from the carelessness or tardiness of the physician. In many cases no physician is called. In others the fear of quarantine leads to concealment. Hence it need not surprise us that the total number of cases of communicable diseases returned in 1908 was 113,357 as compared with 70,864 in 1907. An increase of 37 per cent. in a single year is of course not for a moment to be thought of and can only be attributed to increased faithfulness on the part of physicians in reporting and increased vigilance on the part of health officers and registrars.

Scarlet Fever has been extremely prevalent all over the State. It has, however, been of the same mild type which has marked it of late years.

Measles, too, has been epidemic in many places. Until the popular heresy that this is so mild a disease as to be negligible and that it is a good thing for children to "have it and be over with it," ceases to be held, this disease will continue not only to reap a large harvest of young lives, but to leave in its train an army of the blind, the dumb and the consumptive to be a burden on the community.

It is encouraging to notice that physicians are becoming alive to the importance of reporting that serious contagious infection of the eye, Trachoma, which is responsible for so many cases of blindness.

WORK DONE BY HEALTH OFFICERS OF THE DEPARTMENT FOR THE YEAR 1908.

No. of reports received from physicians,	30,671	
No. of premises placarded,	12,369	
No. of quarantine permits issued,	8,634	
No. of premises disinfected,	13,705	
No, of rooms disinfected,	27,290	
Total amount of air space in cu. ft. disinfected,	29,686,501	
Total number of pts. of Formaldehyde used,	297,045	
No. of measures of Potassium Permanganate used (8 oz. to the measure),	312,348	
Bichloride of Mercury used,	153	bottles
Carbolic Acid used,	35	lbs.
Sulphur used,	420	"
Lime used,	1,014	"
Chloride of Lime used,	114	"
No. of Creameries inspected,	178	
No. of Dairy inspections made,	15,359	
No. of schools inspected,	19,027	

MORTALITY.

The total number of deaths in the State for the year was 112,246. This was a decrease as compared with the year before of 3723.

The principal cause of death was Tuberculosis, which claimed 10,180 victims. Of these 8,688 perished from the pulmonary form of the disease and 1,492 from other forms. Pneumonia was an easy second in the race of death, carrying off 7,264. This, however, was a diminution from the showing of the year before, which was 7,849, a decrease of 585.

COMMUNICABLE DISEASES.

SMALLPOX.

We are fortunate in being able to record the fact that during the year not a single death from this disease took place. This is a decrease of a hundred per cent. from last year, when one death was reported.

From one point of view, however, it is not so fortunate, as it will throw our people off their guard and thus strengthen the argument of the antivaccinationists that smallpox is now a negligible disease and that vaccination is, therefore, an unnecessary hardship. No doubt the next Legislature will see a renewal of the hysterical efforts which were made before the last Legislature to procure the repeal of the excellent law which makes vaccination a pre-requisite to admission to school.

TUBERCULOSIS.

The mortality from Tuberculosis in all its forms amounted to 10,211, a decrease of 614 from the year 1907.

While this is gratifying as a general statement, still more gratifying is it to be able to state that all of this decrease was in pulmonary tuberculosis, against which the Department has been making its especial fight, the actual decrease having been 614, a reduction of more than six per cent.

TYPHOID FEVER.

This disease, which is the special opprobrium of Pennsylvania, carried off 2,450 of our population. This is fewer than the number of typhoid deaths for 1907 by 1,088, a reduction of more than 30 per cent. When it is remembered that the 1907 report showed an improvement over 1906 of 379, it is impossible to escape the conviction that the faithful labors of the agents of the Department in the removal of sources of pollution from the watersheds combined with the improvements in municipal water supplies, the latter principally in the matter of filteration, are bearing fruit. The reduction in three years has been from 56.5 per hundred thousand in 1906 to 50.3 in 1907 and 34.3 in 1908.

SCARLET FEVER.

The deaths from Scarlet Fever were greatly in excess of those for the year previous and indeed for many years, reaching the figures of 1,217, the tendency to increase malignancy as well as to numerical increase observed in the last report having continued throughout the year

Measles also exhibited increased virulence, having caused 1,215 deaths, as compared with 714 in 1907, and more than scarlet fever.

Whoopingcough was responsible for 1,264 deaths, 23 less than in the preceding year and 286 fewer than in the year before than. Measles and whoopingcough combined, therefore, carried off 2,481 children, notwithstanding that they are so lightly regarded by the public.

Diphtheria is credited with 1,970 deaths. This is a gratifying diminution from the year 1907, which also showed a decrease from 1906 of 300, the decrease in the two years since the free distribution

of antitoxin to the indigent by the Department began having been 468. As pointed out by the Registrar of Vital Statistics, if the same death rate from diphtheria as prevailed in the U. S. registration area in 1890 had prevailed in Pennsylvania in 1908, the number of deaths would have been 6,980 instead of 1,970.

The attempt by the Department to fight Malaria and therefore to abate the Mosquito pest, which is responsible for it, was by the majority of people looked upon as chimerical. Our tables, however, seem to show that we are actually making headway in this unequal contest, the number of deaths from Malaria having been 99 in 1906, 81 in 1907 and only 44 in 1908, a diminution of more than one-half in two years. This certainly is a sufficient reply to the inquiry whether the Department was justified in making a mosquito survey of the State.

HOUSE AND ROOM DISINFECTION.

The duty of disinfecting premises after the presence of an infective disease is assigned to the Health Officers. For the destruction of the germs of communicable diseases the Department depends principally on the action of formaldehyde gas, as evolved from an official (U. S. P.) thirty-seven and a half per cent solution, by the action of Potassium Permanganate, in an apparatus provided by the Department.

The dimensions of this vessel have been fixed by empirical trial as ample for the diffusion of the gas, thus preventing its ignition when in contact with a live flame, an accident which might have most serious consequences. Each health officer is furnished with a supply of chemicals, the unit of supply being 5 pounds of formaldehyde and 22 pounds of potassium permanganate. During the year 3,485 units have been sent to the different health officers, besides 176 pounds of formaldehyde, and 170½ pounds of Permanganate, making a total of 153,516 pounds of Formaldehyde, which equals approximately 17,425 gallons, and 76,777 1-2 pounds of Potassium Permanganate.

Health Officers are instructed to notify the Department when their supply of disinfectants is running low, so that they may be ready for any emergency.

DIVISION OF LABORATORIES.

While the physicians of the State have been quick to appreciate and avail themselves of the immense advantages afforded them in the matter of diagnosis and prognosis by the laboratories of the Department. they have not yet learned the importance of furnishing clinical data and other information together with their samples, and this has greatly delayed the service by reason of the time consumed in correspondence.

Daily reports have been made to the Division of Medical Inspection by my instructions in order to act as a control on the Morbidity reports of communicable diseases. The rapid increase of work has necessitated the appointment of a Diener of Supplies to care for all outfits for the sending of specimens. The number of examinations made during the year has been 9,065, more than twice as many as during 1907, the greater number being in sputum and water.

During the year our Chief Bacteriologist has introduced improved methods of analysis of water, enabling us to differentiate the Bac. coli from allied species in water, making the diagnosis more exact and greatly shortening the time required for the search of this micro-organism.

The research work has been continued, covering investigations on the products of the tubercle bacillus and efforts at the production of immunity, the effects of repeated injections of Old Tuberculin in cows, the similarity between Barium Carbonate Poisoning and Rabies in dogs, and the study of the specimens from a case of combined leprosy and tuberculosis. Full details will be found in the report of this Division.

Experience has demonstrated that the examination of the sputa of tuberculosis patients is by no means devoid of danger to the examiner and even to others working in the laboratory. A device was introduced early in the year with the object of minimizing this risk as far as possible. This consisted in the erection of a cage over the desk at which the spreading and drying of the sputa is done. This was made by supporting a glass plate on the sides and front by a wooden frame fitted with a wire screen, and so slanted that it shall be two inches higher at the back than at the front.

At the back is a solid wooden partition, from which a vent leads to a six-inch galvanized iron pipe containing a large Bunsen flame. All the dried particles escaping into the air go up this flue and are destroyed by the high temperature of the air or walls. The top of the shelter is hinged so that it can be lifted when not in use. When the specimens are dry they are rendered innocuous by fixation in the flame. Notwithstanding the liberal accommodations furnished us by the University of Pennsylvania, the work is growing to such an extent that the possibility of being forced to seek additional space outside is forcing itself upon us.

SCHOOL INSPECTION.

Early in the year the following instructions were sent to the township health officers:

"The second inspection of township schools in your district is hereby authorized.

Advise us forthwith of the number of schools in *each township* in your district that we may make permanent records of same and send you Form 51.

When making returns note on the reverse side of the sheet existing nuisances or conditions otherwise prejudicial to the health of pupils, as well as sanitary improvements in such conditions effected since your first inspection.

In addition to answering the question on the blanks you will please note on the reverse side of the blank the schools not complying with the following laws, and mention specifically wherein the respective requirements have been violated in each instance.

'That boards of schools directors and controllers shall provide suitable and convenient water-closets for each of the schools under their official jurisdiction, not less than two for each school or school building, where both sexes are in attendance in their respective school districts, with separate means of access for each; and unless placed at remote distances one from the other, the approaches or walks thereto shall be separated by a substantial close fence, not less than seven feet in height, and it shall be the duty of the directors or controllers to make provision for keeping the water-closets in a clean, comfortable and heathful condition.'

'That the boards of school directors and controllers of each school district of this Commonwealth be and they are hereby required at least once during each full school term, and prior to the first of January of each year, and within thirty days after the close of each annual school term, to have taken out, removed and hauled away all excrement and waste matter from every outhouse or water-closet connected with or standing upon the premises of every public school house in the Commonwealth or have the same properly disinfected; and they are required to have every outhouse or water-closet properly scrubbed, washed out and cleaned, the inside walls whitewashed and the vaults or receptacles covered with a layer of fresh dirt or slacked lime within ten days of the opening of each annual school term.'

On a separate sheet of paper, but attached to each school inspection blank, we desire you to copy the names of unvaccinated school children attending school, as well as the name and address of their parent or guardian as recorded in the school register, observing the following arrangement:

Pupil, ... Parent, ... P. O. Address, ...

Observing the same arrangement, record on an additional sheet (also appended to the blank) the names of all children debarred from this school for not complying with the vaccination law.

Your are to take no action otherwise, and any remarks that may occur to you should be made *only* to the Department on the separate sheet upon which such names are recorded."

The results of this inspection are seen in the following report. It will be observed that the school directors in the country are far from appreciating the requirements which the Legislature makes for the observation of the laws not of sanitation only but even of decency. Still a slight improvement may be noted over the conditions observed last year.

The apparent discrepancy between the rating of the schools for the Spring and Fall inspections for this year does not indicate, as

might at first appear, a deterioration in the condition of the schools in the Fall as compared with that in the Spring, but simply a difference in the plan of rating, with greater precision as to details and more care in analysis. The general designation of "sanitary" appeared unsatisfactory and was therefore omitted.

DAIRY INSPECTION.

Every community of any size in the State avails itself of the law to prevent the sale of impure or adulterated milk, but this effort only touches the circumference of the evil produced by the consumption of infected or filthy milk. The place to attack this serious source of disease is rather at the centre, where the milk is produced. For this reason I waited only until a sufficient number of township health officers had been appointed and had become somewhat familiar with their routine duties, to institute a systematic inspection of the dairies of the State, with a view to eventually weeding out all such as failed to conform to the regulations prescribed by the Department and thus securing an approximately pure food supply of this most important of our food products, especially important during the period of infancy.

It is true that some cities had already adopted a scheme of inspection of their own, but this was always rendered more or less ineffective by reason of absence of legal authority and could not be accomplished without the permission of the dairymen. With an absolute knowledge of the responsibility of this article of food for the spread of many of the most common communicable diseases on the one hand and of the comparative ignorance of the average farmer of the precautions necessary to be used to protect its purity on the other, the duty of the Department seemed very plain. In the month of July, therefore, the following letter of instructions was issued to the township health officers:

"To the Health Officer.

Dear Sir: We enclose dairy inspection blanks with the request that all dairy farms supplying milk to the general public in your district be inspected prior to August 20th.

We wish you to learn the name and location of dairymen, arrange your route and complete the work with as little expense and loss of time as possible.

See that all questions are answered definitely and legibly, leaving nothing for conjecture.

In answering question No. 5, 'Is it polluted?' it should be borne in mind that any water supply which receives drainage from sewers, privies, barnyards, manure piles, slaughter houses or industrial waste can only be considered as polluted. If you report pollution

of any water supply the evidence of such pollution should be apparent to the casual observer. Question No. 7 is especially important. The presence of stagnant pools, streams or swamps receiving sewage, through which the cattle may wade should be noted.

With regard to the cooling of milk, the appearance of the water in the cooling tank should be noted, whether it is clean and without sediment or whether ill-smelling, with or without sediment.

In view of the natural feeling that a man's home is his castle and that conditions existing thereon are matters of purely personal responsibility, the Health Officer's attitude must at all times be kindly considerate and his remarks free from criticism. The Health Officer is sent to the premises to obtain information only and the questions asked should be presented as tactfully as possible in order that no antagonism may be aroused. Our work is in the interest both of the milkmen and the consumers. The Department's aim is to be helpful to the farmer and not meddlesome.

After securing the data required, a copy of the accompanying circular of suggestions should be given to the farmer, with the request that same be tacked up in the stable.

Should any difficulty be encountered a detailed report of same should be made to this Department forthwith.

If more inspection blanks are required, advise us at once. If the whole supply is not needed, return those not required."

The following is a copy of the card furnished the inspector to guide him in his investigation:

COMMONWEALTH OF PENNSYLVANIA,
DEPARTMENT OF HEALTH.
SANITARY INSPECTION OF DAIRIES.
FOR THE PURPOSE OF
PROTECTING THE MILK FROM DIRT AND DISEASE PRODUCING GERMS.

Owner of Farm,
P. O. Address,
Township,
Sold at wholesale or retail,
Place marketed,
Name of Dealer,
P. O. Address,

CLEANLINESS OF COWS.

1. Are teats clean?
2. Are udders clean?
3. Are flanks clean?
4. Are tails clean?

WATER SUPPLY FOR CATTLE.

5. From Spring? Running Stream, Public Supply?
6. Is it polluted?
7. If polluted, what from?
8. Can cattle wade in polluted water?

STABLE.

9. Is the floor of the stable clean and dry?
10. Is the ceiling clean?
11. Is the ceiling tight?
12. Is the manure removed daily?
13. Can the cows lie down in their droppings?
14. How is the stable ventilated?
15. Has it sunlight?

COW YARD.

16. Is the stable manure scattered on the ground so the cattle can lie in the same?
17. Are there any pools of manure water in the yard?

MILK HOUSE.

18. If not separate, what else is kept in the same building?
19. Are all the windows, doors and outlets screened from flies?
20. Is there any provision for hot water where the utensils are washed?
21. Are the utensils clean?
22. Is the water supply used in the milk house from spring? Running water? Public supply?
23. Is it polluted?
24. If polluted, from what?

MILKING.

25. Do the milkers wear a clean covering over their clothes when milking?
26. Do they wash their hands before milking?
27. Do they wash the teats and udders of the cows?
28. Are the milking stools which they handle clean?
29. Do they milk the fore milk into the can?
30. Do they use milk on the hands and teats when milking?

HANDLING OF MILK.

31. Is milk cooled immediately after milking? How?
32. What dirty habits did you notice?
33. Has scarlet fever, typhoid fever, dysentery or any diarrhoeal condition existed within the household or among the employes of the dairy farm during the past year?
If so, which? Dates?
Doctor's name?
P. O. Address?

The circular of suggestions to the farmer was as follows:

"TO DAIRYMEN,

My Dear Sir:

Milk being one of the most valuable of food stuffs, the following suggestions are offered that it may be more generally used than at present and to prevent disease that is produced by dirty milk.

THE STABLES.

1. The floors, walls and ceilings of the stable should be tight, walls and ceilings being kept free from cobwebs. There should be as few dust-catching ledges and projections as possible.

2. Do not allow musty or dirty litter or strong smelling material in the stable. It is well to sprinkle the floor with air slaked lime or land plaster daily.

THE MILK HOUSE.

3. Cans should not be taken into the stable to be filled. Remove the milk of each cow at once from the stable to a clean room and strain immediately. Canton flannel or absorbent cotton makes a good strainer. The milk should be cooled as soon as strained. All milk houses should be screened from flies.

4. Milk utensils should be made of metal, with all joints smoothly soldered, or, when possible, should be made of stamped metal. Never allow utensils to become rusty or rough inside. Use milk utensils for nothing but handling, storing or delivering milk.

5. To clean dairy utensils use pure water only. First rinse the utensils in cold water; then wash inside and out in hot water; rinse again; sterilize with boiling water or steam; then keep inverted in a clean place or expose to the sun where no dirt can be blown or dropped into them.

MILKING AND HANDLING OF MILK.

6. The milker should wash his hands immediately before milking. The practice of moistening the hands with milk when milking is most vicious and uncleanly and should be avoided. He should wear a clean outer garment, which should be kept in a clean place when not in use. Tobacco should not be used while milking.

7. The first few drops of milk from each teat should not be milked into the can as it will be apt to injure the milk both as to keeping qualities and as to healthfulness for food stuff.

8. If any part of the milk is bloody, stringy, or unnatural in appearance, or if by accident dirt gets into the milk pail, the whole mess should be rejected.

9. Never mix warm milk with that which has been cooled, and do not allow milk to freeze.

10. Do not feed dry, dusty food previous to or during milking time.

11. Persons suffering from tuberculosis or skin disease, or those suffering from or exposed to those suffering from a contagious disease must not handle either the cows, the milk or milk utensils.

12. It is needless to say that the shorter the time between the production of milk and its delivery, and between delivery and use, the better will be the quality of the milk, providing it is cooled before transported."

The total number of dairies inspected was 17,618. Of these 2,442 were found to be in a condition which entitled them to the highest commendation. Of the remainder many were comparatively clean and carefully conducted but failed in one or more of the eight particulars noted in the card of questions.

For instance, on 480 farms the cattle were found to be drinking polluted water. In somewhat more than twenty-five hundred the floors of the stables were in an extremely filthy condition. In about the same number the milkers did not wash their hands or the udders of the cows before milking or wear clean protective covering to prevent dust and filth from their clothing falling into the milk.

Possibly about half would have passed without criticism by an ordinary uninstructed observer. It was gratifying to discover that so far from appearing antagonistic, the dairymen were generally most ready to co-operate with the agents of the Department in the inspections and to afford every facility, evidently appreciating that it was to their interest to comply with all the instructions furnished by us and thus secure the confidence of the public in the purity of their product.

EPIDEMICS.

TYPHOID FEVER.

The epidemic prevalence of Typhoid Fever in Pittsburgh to an alarming extent led the Mayor of that city to institute a special investigation with the object of discovering its cause. For that purpose he appointed a commission, consisting of three distinguished sanitary authorities from different parts of the United States, and requested me to join them in their study. A full account of the meeting, which took place late in May, will appear under the head of Conferences. During the early part of the year there was little alarming prevalence of the disease in the State, but towards midsummer the excessive drought which prevailed began to deplete the water supplies and intensify the organic poisons which they contained. In January there was a slight outbreak at Reading and in the Lehigh Valley along the Lehigh, Jordan and Little Lehigh Rivers, which called for activity on the part of the Department's officers. In July a threatening condition at Hastings, Cambria County, led the Department to issue a bulletin stating in a general way the measures to be adopted when this disease made its appearance in a community in ferreting out its cause and checking its spread, and which would be pursued by its officers in all cases, thus outlining the campaign which it was forseen was necessarily soon

to be entered upon. This statement, which was given a wide publicity in the public press, was substantially as follows: "When the State Department of Health takes hold of a typhoid fever epidemic with the local health authorities a census is at once taken of the existing cases to learn what possible medium of infection has been common to all or the majority of existing cases. That is, are the victims using the same milk or ice supply; have they been getting shell fish or oysters from the same source, and more particularly, is there a common water supply? Of course, in the meantime, strict precautionary measures have been taken to shut off all possible avenues of infection. "Boil all water and milk" is insisted upon from the first. If the census cases point to an infected milk supply, it is quite possible that upon the dairy farm from which the milk served to these patients has been secured, will be found a case of typhoid fever. If so, this particular supply is at once stopped, and the health authorities do not permit the milk to be marketed until the recovery of the case and thorough disinfection, or unless the milk is handled entirely by persons not living on the premises. If there is any suspicion of the dairy farm water supply prior to examination, the use of such water is not permitted in conducting the dairy. A study of the case, however, may convince the health authorities that the epidemic is the result of a polluted water supply, and a rigid search will probably locate a typhoid fever case somewhere on the watershed. If so, the premises are thoroughly disinfected and all existing nuisances abated. Should the municipality have a storage supply, the reservoir is treated with copper sulphate for the purpose of destroying or inhibiting the growth of bacteria without being harmful to human economy. Where possible, the discharge pipe from such reservoir is elevated so that the discharge of water containing sediment that may be laden with the specific organism of typhoid fever is avoided. A system of flushing the main is instituted, the precaution being observed to thoroughly open and flush household taps and any dead ends that may exist in the system. Where a municipality has no system of sewerage, the Department urges a systematic disinfection of all privy vaults with lime. This is done with a double object—first, to prevent the further spread of the disease through the medium of flies and also to prevent pollution of surface walls, which occasionally follows and prolongs an epidemic, as was the case at Plymouth in 1885.

In fighting an epidemic of typhoid fever or, in fact, all other communicable diseases, it is most important to safeguard the purity of the milk supply. The State Department of Health during the existence of such an epidemic requires the abolition of milk bottles, which are a source of so much danger during epidemics of typhoid and other communicable diseases. Each householder is required

to furnish his own container and into this the milkman is directed to pour the milk without handling or allowing his own can or other vessel to come in contact with that of the householder's. The indestructible milk ticket is also tabooed and milkmen are required to adopt the coupon ticket, that can be used but once and destroyed.

Warning notices are placed on all premises within which there are cases of typhoid fever. This is useful to the nursing corps, which is frequently made up of strangers, and is an aid in carrying out milk regulations. Such warning placards also prevent many people from entering the premises who might be of annoyance to patients and who might carelessly contract the disease themselves.

Warning notices cautioning the citizens to boil all water and milk before use are posted everywhere throughout the town and thus the stranger particularly is warned against the danger of infection.

The employment of a corps of visiting nurses is one of the most efficient weapons in combating an epidemic of typhoid fever. These nurses as they go from one house to another give practical demonstrations of the technique of disinfection. They instruct the members of the household in the precautionary measures that are necessary in order to escape contracting the disease. Such precautionary measures are particularly important in the prevention of secondary cases. The condition of the patient is under the constant observation of the trained eye of the nurse and emergencies are promptly reported to the attending physician.

The physicians of a town are usually taxed almost beyond the power of human endurance at such a time and the service which a well equipped and properly managed corps of nurses can give in fighting the spread of the disease cannot be overestimated.

It has been too common in the past for the town authorities to try to suppress all news of the presence of an epidemic of typhoid, whereas safety lies in the widest publicity.

This step was justified by the appearance of the disease in rapid succession in Spring City, Royersford and East Vincent, Chester County; Pottsville, Schulykill County; Easton, Bethlehem and South Bethlehem, Northampton County; Canonsburg and Morganza Reform School, Washington County; Carbondale, Lackawanna County; Wilkes-Barre and Avoca, Luzerne County; Altoona, Blair County; Reading, Berks County; Confluence, Somerset County; Darby, Delaware County. None of these presented any features making it worthy of especial mention except that at Reading. A few cases had been noted in that city in January; these disappeared, and again in August there was a sudden and rather alarming outbreak. This in its turn abated, to a great extent, a few cases, however, continuing to appear until in November they suddenly began to multiply with startling rapidity. The Mayor then applied to this Department for

assistance. The Chief Engineer and the Chief Medical Inspector were therefore despatched on the thirtieth of the month, and joining forces with the local authorities, they immediately inaugurated a campaign as above outlined. Before the end of December 626 cases and 26 deaths had taken place. As the epidemic continued until February, 1909, a full history of it cannot be presented until the report of that year.

EPIDEMIC OF SMALLPOX IN CUMBERLAND COUNTY.

Early in September it was rumored that there was much chickenpox in the eastern part of Cumberland County. An investigation was ordered, and on September 16th twenty-nine cases of true (though mild) smallpox were discovered. Soon after the Postmaster of one of the villages was attacked. The office was immediately closed and thoroughly disinfected and then turned over to the U. S. authorities. Fifty cases occurred before the disease was checked. All the patients were unvaccinated but one, and that one forty years ago. Vaccination within two days after contact usually prevented the development of the disease; but not later. The unvaccinated in the quarantined houses were always attacked.

One hundred and fifty children were kept out of school for eighteen days, making a loss of twenty-seven hundred days of schooling for this little section of the county, vastly more than the vaccination of all the children in the county would have necessitated.

FOURTH OF JULY TETANUS.

As in the previous year a warning was addressed to the public in the hope of diminishing the death list from injuries due to the senseless and barbarous manner in which our national birthday has been celebrated of late years. While it referred to the danger from Tetanus alone it was hoped that the attention of parents and guardians would thus be attracted to the subject in general and that thus a diminution of the evil might be effected. The following was the notice which was widely published by the papers of the State

"Every explosive wound, no matter how slight, should be treated as serious, for the germ of tetanus may be there.

"Not a moment should be lost in sending for a physician, and in the meantime the wound should be carefully washed and then fomented with a hot antiseptic solution. A fatal result may often be prevented by immediate treatment.

"The wound from a toy pistol or other explosive may seem slight. The minute puncture may scarcely leave a trace on the skin. The deadly germ of tetanus, however, may have buried itself in the child's hand and the little one's life may soon pay the penalty."

LEPROSY.

The young Chinese who has been under the combined care of the Department and the health authorities of Harrisburg since July, 1907, died at the close of the present year. The necropsy, the protocol of which will be found later, disclosed the following conditions as the cause of death: Pulmonary tuberculosis with many cavities, bronchopneumonia, and extensive tubercular ulceration of the intestines. The leprosy lesions had made very little progress since he had been under observation.

WORK DONE BY THE COUNTY MEDICAL INSPECTORS FOR THE YEAR 1908.

No of cases examined, reported by Health Officers, supposed to be:	
Variola,	113
Typhoid Fever,	529
Diphtheria,	267
Scarlet Fever,	621
Cerebrospinal Meningitis,	1
Varicella,	660

Typhoid Fever,	188
Variola,	20
Diphtheria,	57
Scarlet Fever,	108
Cerebrospinal Meningitis,	1
Stock ordered transferred on	33
Sale of milk stopped on	93

CONFERENCES, CONVENTIONS AND ADDRESSES.

EASTON.

On February 14, 1908, I met the citizens of Easton in mass meeting by the urgent request of the authorities, the occasion being the discussion of a proposal to issue bonds to the extent of $241,000.00 for the purpose of constructing a sanitary sewer, and the vote to be taken on the Tuesday following.

The situation arose out of the fact that inasmuch as the city of Easton had failed to hand in to the Commissioner of Health plans of its sewer system within the limit of time fixed by the law it thus made itself liable to State prohibition of the extension of its sewers.

The Commission, consisting of the Governor, the Attorney General and the Commissioner of Health therefore refused to issue such permit on the ground that the general interests of the public health would not be subserved thereby, as the system is at present constructed.

It was to provide for the substitution of a complete modern system instead of the old imperfect and antiquated system that the bond issue was proposed.

I endeavored to make the situation entirely clear to the meeting, and then appealed to the patriotism and humanity of the citizens not to continue to poison the waters of a stream which was used as a source of drinking water by so many hundred thousand of their fellows.

PENNSYLVANIA STATE COMMITTEE OF THE INTERNATIONAL CONGRESS ON TUBERCULOSIS.

On the 24th of February, 1908, a meeting of the Pennsylvania State Committee of the International Congress on Tuberculosis was held in the office of the Commissioner. The Commissioner, as Chairman, presided and took occasion to define distinctly the limitations of the scope of the Committee as distinct from that of the State Department of Health in the matter of exhibits.

Several subsequent meetings of this Committee were held at the same place.

ALUMNI OF LAFAYETTE COLLEGE.

By invitation of the faculty of Lafayette College I addressed the Alumni of that institution at their anniversary meeting in commemoration on the founding of the college, held in Philadelphia, March 12, pointing out the necessity for the co-operation of educational bodies with the State departments which are striving for the uplift of the people.

THE ACADEMY OF NATURAL SCIENCES.

March 28, in response to a request from the Biological Section of The Academy of Natural Sciences of Philadelphia I read a paper on "What the Miscrope has done for Medicine."

MEDICAL CLUB OF PHILADELPHIA.

On April 10th, in acknowledging the compliment of a reception by the Medical Club of Philadelphia, I took occasion to urge the importance of the active and earnest support of the medical profession in the efforts of the State to check the spread of epidemic diseases, and to express my appreciation of the aid already given.

AMERICAN SCHOOL HYGIENE ASSOCIATION.

In response to a request from the American School of Hygiene Association I presented a paper at the meeting of that body at Atlantic City, April 17, on "The Medical and Sanitary Inspections of Schools and their Relation to the Tuberculosis Problem.

ANNUAL CONFERENCE OF STATE AND TERRITORIAL BOARDS OF HEALTH WITH THE SURGEON GENERAL OF THE P. H. AND M. H. SERVICE.

Being unable to attend the annual conference of the State Boards of Health with the Surgeon General of the Public Health and Marine Hospital Service at Washington, April 27th, I commissioned Dr. Herbert Fox, the Chief of the Laboratories of the Department, to represent the State on that occasion.

MEETING OF THE COUNTY MEDICAL INSPECTORS FOR THE STUDY OF TUBERCULOSIS.

In taking up the grave duty of the adoption of means to prevent the spread of Tuberculosis in the State, a duty imposed upon the Department by the last Legislature, it seemed desirable to establish a well equipped Tuberculosis Dispensary in every county. It also appeared wise to assign the duty of conducting these dispensaries, so far as possible, to the County Medical Inspectors of the several counties. This, of course, made it necessary that these officers should be men in the prime of life and full of vigor of health, and should also possess a reasonable knowledge of modern methods of diagnosis of the disease in question. Certain changes in the personnel of this corps therefore became unavoidable.

Furthermore, as the opportunities for physicians living remote from the great medical centres for becoming familiar with the niceties of manipulation and use of instruments of precision in the study of pulmonary affections introduced of recent years are extremely rare, it seemed important for the credit of the Department, for their own satisfaction and for the welfare of the State, that the physicians, taking up this special line of work, should be afforded occasions of witnessing demonstrations and listening to lectures by acknowledged leaders in the diagnosis of tuberculosis.

The first meeting of this kind took place in the city of Philadelphia, Tuesday and Wednesday, May twelfth and thirteenth, 1908.

Arrangements had been made with prominent medical teachers of that city, who had given especial attention to this department of medicine, and who kindly volunteered their services to deliver a series of clinical lectures on the diagnosis of the disease in its various phases. The subjects were assigned as follows: To Dr. William E.

Hughes, Philadelphia General Hospital, "Miliary Tuberculosis;" to Dr. Alfred Stengel, Hospital of the University of Pennsylvania, "Pulmonary Tuberculosis," to Dr. James M. Anders, Medico-Chirurgical College, "Tuberculosis of the viscera and serous cavities;" to Dr. James C. Wilson, Jefferson Medical College, "Tuberculosis in Children." Visits were also planned to the Laboratories of the Pennsylvania Department of Health at the University of Pennsylvania and the Bacteriological Laboratories of the Philadelphia Zoological Gardens, in which so many researches have been prosecuted on tuberculosis in animals.

The members of the Advisory Board and the heads of the several Divisions of the Department also attended the demonstrations, which were most instructive. I took occasion to address a few words to the assembled inspectors on the subject of their relations to the Department and their general duties as well as their special work in connection with the dispensaries. The opportunity for personal intercourse and interchange of views and experiences between the inspectors must result in mutual improvement and in the development of an esprit de corps which cannot but be most beneficial.

MEETING OF THE COMMISSION TO INVESTIGATE THE CAUSES OF TYPHOID FEVER IN AND ABOUT PITTSBURG.

On May 22nd I attended a meeting of the Commission appointed by his Honor, Mayor Guthrie, of Pittsburgh, and the Director of the Russell Sage Foundation, to inquire into the origin and prevalence of Typhoid fever in and and in the neighborhood of that city and to determine its cause or causes. It consisted of J. F. Edwards, M. D., Superintendent Bureau of Health, Chairman; Samuel G. Dixon, M. D., State Commissioner of Health; John W. Boyce, M. D., Pittsburgh; W. T. Sedgwick, Ph. D., Mass. Institute of Technology; Milton J. Rosenau, M. D., Director Hygienic Laboratory, U. S. Public Health and Marine Hospital Service; Morris Knowles, C. E., Consulting Engineer; Frank E. Wing, A. B., Assoc. Director, Pittsburgh Survey, Secretary and Treasurer; and E. G. Matson, M. D., Executive Officer.

The subject was discussed from all points of view and a committee was appointed to formulate a report.

CONFERENCE WITH FORESTRY COMMISSION.

On June 10th I met the Forestry Commissioner of the State and other members of the Forestry Commission and of the School of Forestry, explained to them the modern theory of the treatment of Tuberculosis, and accompanied them in an inspection of the State South Mountain Sanatorium for Tuberculosis at Mt. Alto, Franklin County.

PAN-AMERICAN MEDICAL CONGRESS.

The Pan-American Medical Congress held its annual meeting at the city of Guatemala on August 5th, and the U. S. Government commissioned me to represent it. Being unable on account of the length of time which it would have consumed to attend, I forwarded a communication to the Secretary, in which I gave a detailed statement of the history and working of this Department, accompanied by documents and forms.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Being for a similar reason prevented from attending the annual meeting of the American Public Health Association at Winnepeg, Manitoba, I contributed a paper on "Measures to promote the Health of School Children," which was read by Dr. Wilmer R. Batt, State Registrar, who was commissioned to represent the Department on the occasion, which took place August 25-29th.

CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH OF NORTH AMERICA.

On September 19th the Department was represented at the Annual Conference of State and Provincial Boards of Health, held at Washington, by Dr. Wilmer R. Batt, State Registrar, who presented a paper on "Suggestions for New Regulations for the Transportation of the Dead."

SEVENTH INTERNATIONAL TUBERCULOSIS CONFERENCE.

At Philadelphia, September 25th, I attended the Seventh International Conference on Tuberculosis, and read a paper on "Legal Rights and Tuberculosis."

INTERNATIONAL CONGRESS ON TUBERCOLOSIS.

From September 28th to October 3rd I attended the meetings of the third International Congress on Tuberculosis at Washington as Vice-President of the Section on State and Municipal Control of Tuberculosis, and presented a paper on "The Governmental Control of Tuberculous Patients in Pennsylvania."

The Department was also represented by Dr. Wilmer R. Batt, State Registrar, and Dr. T. N. McKee, County Medical Inspector, who were in charge of the installation, care and demonstration of the Depart-

ment's exhibit, and by Private Secretary Wilbur Morse, Dr. Benjamin Lee, Assistant to the Commissioner, Chief Engineer F. Herbert Snow, Dr. Thomas H. A. Stites, Medical Inspector of Tuberculosis Dispensaries, Dr. F. C. Johnson, Chief Medical Inspector, Dr. A. B. Moulton, Assistant Medical Inspector, and by County Medical Inspectors Joseph Scattergood, J. C. Reifsnyder, Charles H. Miner, Edgar M. Green, all of whom gave demonstrations, and Dr. A. M. Rothrock, Resident Physician of the Mont Alto Tuberculosis Sanatorium. A paper was read by Dr. T. H. A. Stites on the day known as "Social Workers' Day," on the "Tuberculosis Dispensaries of the Department of Health of Pennsylvania."

Although I had expressly stipulated in sending the exhibit that it should not be considered as "in competition," the Committee on Prizes and Awards saw fit to make the following awards. "Gold Medal to the Department of Health of the State of Pennsylvania in recognition of its work in establishing a magnificent system of dispensaries and sanatoria."

"Silver Medal to the State Department of Health of Pennsylvania for a model cottage for incipient cases of tuberculosis."

"Honorable mention to the Department of Health of the State of Pennsylvania for twelve beautiful autotone films of human lungs, showing tuberculosis conditions, this being the first application of this process in medical uses.

Silver Medal to the State of Pennsylvania for best exhibit of any State of the United States illustrating organization.

ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

The 58th Annual Session of the Medical Society of the State of Pennsylvania was held at Cambridge Springs, September 15-17. The Department was represented by Dr. A. B. Moulton and Dr. T. H. A. Stites, Inspector of Tuberculosis Dispensaries, the latter of whom presented a paper before the Section on Medicine on "The Dispensary System of the Pennsylvania Department of Health. A sketch of its Organization and Methods."

ANNUAL CONFERENCE OF SANITARY OFFICERS OF THE STATE OF NEW YORK.

By invitation from Dr. Eugene Porter, Health Commissioner of the State of New York, on December 3rd I attended the annual conference of the Sanitary Officers of the State of New York at Albany, and at his suggestion addressed the members on "The Public Health Administration in Pennsylvania."

STATE COLLEGE OF PENNSYLVANIA.

"Farmers' Week."

By request of the Faculty of the State College of Pennsylvania I prepared an address to the assembled farmers and students on the subject, "The Control of Tuberculosis in Man." In this address I called attention to the effort the Department is making to stamp out tuberculosis and to the facilities for diagnosis and treatment afforded by the one hundred dispensaries maintained throughout the State, as well as to the fact that the period of college life is one especially liable to the attacks of the tubercle bacillus. Being prevented by stress of work from visiting the college personally, I deputized Dr. T. H. A. Stites, Inspector of Tuberculosis Dispensaries, to attend and present the address as well as represent the work of the Department in that important field. Occurring as it did on the evening of the last day in the year it formed a fitting close to twelve months of incessant activity on the part of the Department, much of which was devoted to this especial object.

DIVISION OF MEDICAL INSPECTION.

ARTHUR B. MOULTON, M. D., *Chief Medical Inspector.*

THE DIVISION OF MEDICAL INSPECTION

COMMUNICABLE DISEASES.

During the past year this Division has taken part in the suppression of communicable diseases as follows:

SMALLPOX.

CHESTER COUNTY.

Dr. Joseph Scattergood, C. M. I. Coatesville. On December 9th, on receipt of information from Dr. A. Carmichael that a case of smallpox existed just outside of the borough limits of Coatesville, special investigation was begun at once, the diagnosis was confirmed, absolute quarantine was established and the following history elicited: The patient, a young man had been with a threshing crew in the vicinity of Toledo, O., for a considerable time and had left there on the morning of the 5th of December, arriving in Coatesville at 5.40 A. M. Sunday, going immediately to the residence of his father. He gave a history of having been vaccinated in Toledo and of having failed to secure re-vaccination three years ago. Notice was at once sent to the Agent of the Pennsylvania Railroad so that the coach might be located and suitably disinfected.

LINESVILLE, CRAWFORD COUNTY.

Dr. J. K. Roberts, C. M. I., Crawford county. August 7, 1908, Dr. J. K. Roberts writes as follows: "I have the honor to submit to you the following report in regard to the smallpox in Linesville borough and Conneaut township, this county.

"On Monday morning, August 3, I was notified by Dr. Carpenter, one of the physicians of the borough that they had a suspicious eruptive disease in the community and that no doctor had been called and that there was no disposition on the part of the local Board of Health to take action in the case. I immediately visited the case and found the patient had developed variola in the pustular stage and advised that a physician be called. Dr. Collins saw the case with me and agreed with the diagnosis I had made. The case was regularly reported to the local Board of Health and has been properly quarantined." "The Misses E. and F. D., of Erie, had been

visiting in this G. home but had gone home on Saturady previous to the quarantine. I understand that they have been vaccinated. No other precautions were used."

"While investigating the above case I found that the family had recently come to Crawford county from Troy, Ohio, and had been visiting at C. P.'s in Conneaut township. I went to the home of Mr. P. and found him suffering from smallpox in the pustular stage with the date of onset about the same as R. L., in Linesville. I saw that the home of Mr. P. was properly quarantined and inmates vaccinated as well as the homes of W. P. and H. L., of Conneaut township, who had been exposed."

"I understand that there is an epidemic of variola at Troy, O., and that there were twenty cases under treatment when these people left there."

CUMBERLAND COUNTY.

Dr. Harvey B. Bashore, C. M. I. A great many cases of mild smallpox developed in the southern section of Cumberland county during the last quarter of the year. A brief report by Dr. Bashore follows:

"Sometime in August, 1908, a farm hand from Reading came to H. H.'s, back of Camp Hill. He became slightly ill and developed a rash; no doctor. In due time H. and his entire family became sick with the same disease: no doctor. H. had a milk route in the West Fairview-Enola district and continued to serve his customers, although there were many scabs on the face and hands; so much from heresay."

"In September there were cases of chickenpox reported to the Department in the B., H., C., G., and K houses at Enola. B. and H. being related to H. (1), and C. G. and K. being neighbors and visitors at B.'s. These cases reported by four different doctors were claimed to be chickenpox, although in every family adults were affected."

"On September 16, the Department began investigation and found every case to be typical smallpox. The H. house was thoroughly fumigated, and the other families quarantined for smallpox. Meanwhile the health officers were hunting "contacts." Ninety-three families comprising the H. relatives and milk route were put under surveillance. One of these, W. father-in-law to B., having a case in his family, was quarantined. After this only four families became infected. A few more 'contacts' were hunted up and the epidemic at this place ended with C. B., who was quarantined on October 17, and with whom there had been no 'contacts.' In all twenty-nine cases. At the outset of the epidemic Health Officer Hoover resigned, and I immediately sent for Health Officer Weaver, who served me most faithfully.

"On September 17, Postmaster H. walked into my office with a third-day eruption of smallpox, having just returned from a convention at Ford City, Pa., and having left home four days before; he probably contracted the disease from one of the 'perambulating' cases from Enola. The postoffice was immediately closed, thoroughly disinfected and then turned over to the postoffice authorities. I notified the Department of Mr. H.'s trip, his stopping place while at Ford City and the coach on which he traveled. From his case I believe only two or three new ones developed but of this the Department has record."

"Although extreme vigilance was used in hunting 'contacts' one escaped, Mrs. C. W., of New Kingston, related to C., in whose house she probably was the day it was quarantined. She went home and in due time, so the story goes, she herself and children became ill with a rash (no doctor) and the disease was concealed for the time. Her husband became ill and on October 22, the second day of the rash, was found working in McC. store in Carlisle. He was immediately sent home and all 'contacts' in Carlisle vaccinated and put on parole, the local board following my advice in every particular."

"Meanwhile we learned that the W. woman in the role of a book agent, had visited practically every house in New Kingston, and the whole community was put under surveillance. Health Officer Mackey being ordered to take up his residence in the village."

"In fourteen days the first crop of 'contacts' developed in H., H., P., B. and C. M., a teacher in Fairview High School in Middlesex township. All were quarantined and about twenty-five 'contacts' vaccinated and put on parole."

"In fourteen days the second crop developed in the houses of P. and H., already quarantined and only one outside—the B. family which had been under quarantine, they having been vaccinated three days after the contact. In this family one child developed a very modified case which consisted of only five pocks, but they were perfectly typical. Cases in this place all told, twenty-one, making a total of fifty for our epidemic and about four hundred 'contacts.'"

"On December 1, W. W., of Carlisle, who had been in a factory visited by one of the H. children from New Kingston, was found to have smallpox. On December 17, two other families infected by Mrs. K., who evidently had a mild attack, contracted from the same factory, developed. These cases of course belong to the borough of Carlisle."

"While this epidemic seemed to differ in no wise from any other smallpox epidemic, the following facts attracted my attention:

1. The unvaccinated in the quarantined houses invariably got smallpox, except in one instance, while the vaccinated did not get it.

2. Vaccination one or two days after 'contact' generally prevented the development of the disease, three or four days after did not prevent.

3. One hundred and fifty children were kept out of school for eighteen days, which is equivalent to twenty-seven hundred days of schooling lost to the children of Cumberland county on account of smallpox; likely more than would have been lost by the enforcement of the vaccination law.

4. Five (5) doctors called the disease chickenpox although in each house adults were affected.

5. A number of children were reported to be vaccinated and had certificates of vaccination, but were not successfully vaccinated as shown by entire absence of scar.

6. All patients were unvaccinated save one, and that one forty years ago."

DAUPHIN COUNTY.

Dr. Paul A. Hartman, County Medical Inspector. The first case of smallpox in 1908 really commenced in December 17, 1907. This was a mail clerk running between New York and Pittsburg who is supposed to have contracted the disease while handling foreign mail, while on duty in his car. This man while sick and on duty slept in the dormitory both in the New York postoffice and in Pittsburg, giving full opportunity for a great epidemic. From this case we have had but two others in Harrisburg. Great precautions were taken by the Pennsylvania Railroad, the U. S. postal authorities and the city of Harrisburg, in vaccination of mail clerks, disinfecting cars and sleeping quarters of clerks, and the hunting down of contacts for vaccination to the end that an epidemic might not occur, which proved successful. March 10, (1908), I was called to Millersburg to see a subject by Dr. Hottenstein. This case proved to be smallpox in the convalescent stage and was at work in a factory employing several hundred hands, and examination of the hands in the cutting department was made at that time and four or five were sent home into quarantine, they having almost passed through the disease. The factory was temporarily shut down and thoroughly disinfected and then thrown open to the hands. From this epidemic there resulted about 20 to 30 cases (the reports of cases are on file in your office). This trouble was started by a mail clerk in the postoffices of Millersburg, he having had the disease in a mild form which was not recognized and which he contracted by handling mail from the crews in the Pennsylvania Railroad between New York and Pittsburg.

April 11, I saw a case in Halifax. This was a young man who had been exposed to the disease in the Millersburg factory.

On October 3, I was called in to see R. M., living just outside of Harrisburg, in Susquehanna township. He was then in the pustular stage of smallpox. He had been attending a convention of some secret organization in the State and while there roomed with a man who was post-master of a Cumberland county, who was sick at that time with an eruptive disease which proved to be smallpox. Fortunately for us no other cases occurred from this one.

December 19th, a case occurred in the upper part of this city (Emerald St.) in a young woman who conducted a millinery business and who had been in contact with numerous other people. From this case we have to this time (June 20th) but one other, and I believe the trouble is now over. None of these cases had ever been vaccinated.

SMALLPOX IN CONVENTION, FORD CITY, PA.

On the 17th of September, F. H———, Postmaster of West Fairview, Cumberland county, walked into the office of the County Medical Inspector, Dr. H. B. Bashore, with a three-day eruption of Smallpox covering his body. Dr. Bashore in eliciting a history of his illness and travels, learned that this man had just returned from a Convention of the State Council of the Order of Independent Americans in Ford City, Pa., the sessions of which were held on September 15th and 16th, and that the eruption was appearing on his body during a part of the time when he was on the floor of the convention hall. Information of this exposure was at once forwarded to the Commissioner of Health and steps were immediately taken toward learning the name and address of every person attending this Convention, toward learning the destination of the car on which he returned and to give as wide publicity as possible to this information so that those who had been exposed to the contagion of Smallpox might avail themselves of vaccination.

The Secretary of the State Council of this Order, Mr. W. A. Pike, co-operated with the Department of Health in every possible way, sending to the Department a complete list of all the 109 delegates who attended the convention, together with their post-office addresses and street numbers. In addition the following circular was issued by the State Councilor, Mr. Edward Wilson, with the Secretary's attest, and was mailed to each member of the Order.

Organized June 25, 1904. Incorporated July 22, 1905.

STATE COUNCIL OF PENNSYLVANIA

ORDER OF INDEPENDENT AMERICANS

IMPORTANT.

Philadelphia, Pa., September 19th, 1908.

To the Officers and Members of the Councils of the State Council of Pennsylvania, Order of Independent Americans, Incorporated.

Dear Sirs and Brothers:

Your attention is called to the fact that one of the Representatives who attended the Session of the State Council held at Ford City, September 15th and 16th, 1908, was sick with Small-Pox, and was compelled to leave for his home, where he has since been quarantined by the State Department of Health.

On my return to the City, I was immediately communicated with by Dr. Joseph Neff, Director of the Department of Health and Charities of the City of Philadelphia, who requested that we co-operate with the State and City Health Departments to prevent the spread of the disease.

In compliance with that request, I hereby recommend to the members of the Order, and especially to the Representatives and members who attended the Session, to take every necessary precaution by having themselves vaccinated and complying with the requests of the health authorities of their respective communities in which they reside.

This is not only our public duty, but also a possible saving of money to the various Councils, through the payment of sick and death benefits.

A strict compliance with the above will be appreciated.

Fraternally yours,

EDWARD WILSON,

State Councilor.

Attest:

WM. C. PIKE,

S. C. Secretary.

On receipt of the list of delegates the Department got into telephonic or telgraphic communication with the Secretaries of the Boards of Health of each of the districts whence these delegates came, and within a few days all of them were offered vaccination and placed under observation.

Notice was at once sent to the Superintendent of the Railway Mail Service telling him that the Postmaster had sickened with smallpox and with his co-operation the Postoffice building and all mails were disinfected; the mails which had been sent from West Fairview to Harrisburg were apprehended and together with the Harrisburg Post Office were disinfected. Fortunately but a single mail had left the Post Office and it was easily located in Harrisburg and held for proper disinfection.

The coach of the Pennsylvania Railway on Which Mr. H———, returned from Ford City was located and disinfected, as well as the electric car on which this man traveled from Harrisburg to West Fairview.

It is very gratifying to note that but three of those who came in contact with Mr. H———, sickened with smallpox. R. M———, No. 1834 State Street, Harrisburg, who slept with H———, in Ford City, sickened on September 28th—the characteristic eruption of smallpox appearing on October 1st. E. E———, a delegate to this Convention, living in Coventry township, Chester county, sickened about the first day of October with smallpox of a mild type; and M. C———, an unvaccinated girl of 14, at the residence of M. S———, in West Fairview, developed the disease about the 1st of October. She had probably come in contact with this man at the Post Office.

While it is gratifying to find so many of these men willing to cooperate with the Department and have vaccination practiced at once, it is doubly gratifying to know that where these contacts refused vaccination and contracted the disease with the rigid quarantine regulations established and thorough vaccination practiced no secondary outbreaks occurred.

SMALLPOX IN THE RAILWAY MAIL SERVICE.

About the 16th of December, 1907, a case of smallpox developed in a clerk in the Railway Mail Service of the Pennsylvania Railroad. In spite of active cooperation on the part of the Railway Mail and widespread disinfection of dormitories, coaches, etc., three cases subsequently developed and gave the Department considerable anxiety during the entire month of January. It is indeed a pleasure to note the cordial co-operation of Mr. V. J. Bradley, Superintendent of the Mail Service and Mr. Burkhill, Superintendent of the Harrisburg Service. The following special orders were issued to assist the Department in stamping out the infection.

"On account of three cases of smallpox having developed among the New York and Pittsburg clerks between December 16th and 31, precautionary measures of fumigation were generally taken and all clerks on the line instructed to be vaccinated. As nearly three weeks had elapsed since the last case was reported there was reason to

believe that these precautions had been effective and final. A case of smallpox is now reported on the Elmira and Baltimore line, and it is necessary that all clerks running in connection with the New York and Pittsburg or Elmira & Baltimore lines be vaccinated if they have not been recently vaccinated, and in either case submit certificate to the Chief Clerks at Harrisburg or Williamsport to this effect. It is desired that this action be taken immediately and Chief Clerks will report any undue delay.

A number of cases of smallpox are reported in New York State, although not in the R. M. S., and it is therefore recommended that all clerks running in the Second Division be vaccinated without delay, not only as a duty to the position they hold, but in the interests of themselves and their families." (Issued 1-24 & 1-27-08).

"In order that the Post Office Department and the Department of Health of Pennsylvania may be assured that the clerks of this Division, referred to in General Order No. 4393, Sec. 44, dated Jan. 27, 1908, are immune from smallpox, it is necessary that all of these clerks submit to their Chief Clerks certificates of successful vaccination. Arrangements have been made by which the Medical Examiners of the Pennsylvania Railroad Relief Association will examine the cicatrix on these clerks and endorse their certificates when their vaccinations are found to have been successful. These examiners will be found at their offices during the business hours of the day at Pittsburg, Harrisburg, Williamsport, Philadelphia, Trenton and Jersey City. Where it is not convenient or practicable for a clerk to call at the office of any of these Examiners, he may have such examination and endorsement made by any physician representing the Pennsylvania State Department of Health. No fee will be charged for these examinations.

The Chief Clerks at Harrisburg and Williamsport will supply clerks with blank certificates (Form 11) for this purpose, and clerks will be expected to give this matter immediate attention." (Issued 2-26-08).

As rapidly as contacts were located in these cases the Boards of Health throughout the State and in adjoining states, were warned and within a few weeks the conditions were brought under control. In order that the Department of Health should assist the Railway Service in enforcing the orders requiring vaccination certain of our County Medical Inspectors were detailed to inspect vaccination scars at terminals and stations where numbers of these employees were apt to report and in this way the entire corps of Railway Clerks were satisfactorily vaccinated, or were forced to submit for inspection scars showing a good vaccination.

In addition to securing the services of our County Medical Inspectors for this verification, through the good offices of Dr. Casper Morris, Chief Medical Examiner for the Philadelphia & Reading Relief Association and Dr. Samuel W. Latta, Chief Medical Examiner of the Pennsylvania Railroad Voluntary Relief Department, certain of their Medical Examiners already commissioned as special Inspectors of the Department for their roads were called upon to assist

in this work. Through the combined offices of all these medical men more than five hundred certificates of vaccination were inspected and verified and nearly as many Railway Clerks were vaccinated.

As will be seen by referring to the orders, these precautionary measures extended to the states of New York, New Jersey and the adjoining divisions of the Railway Mail Service and resulted in general observation of vaccination.

FAYETTE COUNTY.

Lemont. On receipt of telegraphic information that a smallpox case had been reported at Lemont, Fayette county, an investigation was undertaken by Dr. C. B. Wood, County Medical Inspector for Washington county, in which he found the attending physician and Health Officer had already secured absolute quarantine with guards and was actively engaged in vaccinating all contacts.

"This young man arrived in New York City on the Baltic—one of the White Star Liners,—on the 14th of March, 1908, going directly to Lemont, Clearfield county, thence to Lemont Furnace, Fayette county. The eruption of smallpox appeared on the 26th of March and was diagnosed by Dr. Salisbury, the attending physician on the 27th.

The patient is 24 years of age and gives a history of having been successfully vaccinated at the age of one year and of never having been revaccinated.

All contacts were held under observation until the period of incubation was over and several of them were provided with the necessities of life during this time, through the good offices of the Superintendent of the A. C. Frick Coke Company.

LEHIGH COUNTY.

New Smithfield. Dr. M. F. Cawley, C. M. I. "On receipt of a telephone message, March 30th, from Dr. Hottenstein, Kutztown, reporting a case of smallpox at New Smithfield, in the family H. G———, an immediate inspection was made. The patient was found to have varioloid; his wife and the other members of the family were vaccinated and the usual quarantine with guards was established. On obtaining a history of two persons having visited this man, I began to search for the contacts and found that M. F———, aged 23, was then in the third week of the disease. The attending physician had pronounced this latter illness chickenpox and mumps. The usual quarantine was established and the names of other contacts were secured and the cases investigated. This investigation revealed no more cases of smallpox but did uncover several unreported cases of chickenpox and led to the proper disinfection after this disease.

It is very gratifying to the Department to know that after rigid quarantine had been established and vaccination practiced no secondary cases developed.

SCARLET FEVER.

ALLEGHENY COUNTY.

Dr. S. M. Rinehart, C. M. I. On receipt of telegraphic orders, September 8th, special investigation was made of alleged breaking of quarantine on the premises of R. D. W———, of Verona, on the part of the Librarian of the Carnegie Library at Bessemer in Penn township. By special arrangement with this man and the local Health Officer, careful disinfection of his personal clothing was performed and an antiseptic bath was taken and the gentleman removed to a house with the distinct understanding that he would remain away from his home until quarantine had been lifted.

ARMSTRONG COUNTY.

Gilpin Township. Dr. T. N. McKee, C. M. I. At the request of Mr. C. G. S———, a school director, I visited Gilpin township where I found that two children with well marked scarlet fever have been attending the Riggle School in said township for some days. I also found two other cases in that district—one confined to bed and the other to his room—with the same disease.

In order to protect those not already infected I ordered the school closed until the building was thoroughly disinfected. The Health Officer was directed to enforce the usual rules in the house where the disease exists."

BRADFORD COUNTY.

Dr. S. M. Woodburn, C. M. I. An unusual amount of scarlet fever was present throughout the entire county during the year, morbidity rates from this disease running unusually high from the boroughs as early as April—the greatest prevalence in the rural districts being reached during August, September and October. The Department was called upon in many instances to render aid.

EAST TROY.

By order of the Department a visit was made to East Troy February 7th to investigate alleged violation of quarantine in regard to scarlet fever where "I found that there were two cases of scarlet fever, one at L. V———, and one at C. L———, both under quarantine. At V——— some 23 cows were milked and the milk taken to the creamery. V——— was helping with the milking and helping to care for the sick child. I informed him that he could not be per-

mitted to have anything to do with the milk or milk utensils, if the milk was disposed of to the public. He promised to make other arrangements for caring for the milk."

"It appears that there were a couple of cases of scarlet fever in that vicinity the latter part of December in which the quarantine was not well observed. They have recovered, the houses have been disinfected and the quarantine has been lifted.

WYALUSING TOWNSHIP.

In Wyalusing township in a community of four or five families of lawless individuals eleven patients were found sick with scarlet fever at the same time. It became necessary to provide absolute quarantine and place a guard to enforce it in order to preserve the regulations of the Department.

COLUMBUS TOWNSHIP.

A special inspection of the dairy farm of T. A———, in Columbus township, was made. The dairyman was found in contact with his three children ill with scarlet fever and was taking care of 15 cows and delivering milk to a creamery twice a week. He was ordered to take an antiseptic bath, put on a clean suit of clothes, to remain out of the house during the illness and to make special provision for handling the milk utensils at a point far enough distant from the house to be free from danger.

SPRINGFIELD TOWNSHIP.

On July 16th special investigation was made of quarantine conditions on the dairy farm of R. Y———, in Springfield township, and the regulations of the Department were found to be neglected. Strict enforcement of the regulations was instituted and satisfactory arrangements made for the complete isolation of the patient and her care taker during the remainder of the illness.

WYALUSING TOWNSHIP.

On receipt of information that scarlet fever was prevalent in Wyalusing township and the cases were not being treated by a physician a special investigation was made on the 21st of September, resulting in the location of a nine year old girl, L. L———, who had been in attendance at the Wyalusing School typically ill with scarlet fever; in finding a five year old girl, P. Y——— in the home of F. E———, about two miles from this school, in an active stage of desquamation

one month after the onset of what was believed to have been scarlet fever, and in the locating of what was believed to have been scarlet fever in the home of F. E——— and H. Y——— in the same community. Patients in both instances being well and through desquamating. It is probable that through these sources others were infected.

STEVENSVILLE.

Under order from the Department a special investigation was made at Stevensville on the 10th of November; "I found four families under quarantine in Stevensville and vicinity for scarlet fever. L. G———, 21 months' old babe had it some three weeks ago. Three children in the family that have not had the disease. A girl thirteen years old at home of J. G——— had the disease three weeks ago. Six younger children in the family have not had it.

The 12 year old daughter of M. W———, living two miles from Stevensville, was taken with it about three weeks ago. I passed Mr. W——— on the road with his team coming from the mill. He said he had a permit from the Health Officer. On inquiry he admitted that attendants of the patient came into his room, and on inquiry at the house, learned that he went in and ate with the family in the same room with the patient. Orders were issued that he must stay on his premises until disinfected."

"I found four cases at I. E———'s about four miles from Stevensville, four children seven to sixteen years of age, sick about one week. Three families had been released from quarantine. One case, Geo. C——— had died a couple of weeks ago. He lived alone. The house has been disinfected."

CARBON COUNTY.

Sendel School. Dr. J. K. Henry, C. M. I. A special investigation of an epidemic of scarlet fever in Mahoning Valley in the Sendel School in the early part of March led to the closing of the school and of an investigation of the scarlet fever conditions in the houses of the community. A total of 28 cases of scarlet fever was found in 11 families. Many of these children had not been treated by a physician but certain evidence seemed to show that reports of some of the first cases were suppressed. The physicians who were at fault in each case excused themselves on the ground of not having received from the Department proper cards on which to send notice to the Health Officer.

The usual quarantine was established at each household, the school disinfected and cases were properly kept under observation until the close of the quarantine period. It is probable that from one of these

households infection was carried by a milk supply to a household in the borough of Mauch Chunk. Evidence was not convincing enough to lead to absolute discontinuance of the sale of milk and the transfer of the stock.

By the middle of April the epidemic had practically subsided. The Sendel school was reopened on the 13th of April and the children gradually returned as release from quarantine was granted.

CARBON COUNTY.

Palmerton. Dr. J. K. Henry, C. M. I. An epidemic of considerable proportion was studied in Palmerton on the 18th of May. The onset was supposed to have been about the 5th of May and the early cases were apparently not recognized because of their mild character. Investigation led to the closing of one millinery store and one dental office, the closing of the Sunday Schools for several weeks and the location of a case that had escaped quarantine and succeeded in reaching the town of Bethlehem, where suitable supervision was enforced by the health authorities.

CUMBERLAND COUNTY.

Upper Mifflin township. Dr. H. B. Bashore, C. M. I. The following report received from the Medical Inspector: "I beg to report that I visited the farm of L. M———, Upper Mifflin township, August 22nd, on account of sale of milk from a house placarded for scarlet fever. The neighbors agreed to undertake the milking and marketing of the milk and I therefore permitted the sale to continue."

DELAWARE COUNTY.

Darlington Creamery. Dr. Robt. S. Maison, C. M. I. "On receipt of information from the Health Officer, December 24th, that scarlet fever existed in the family of one of the employees of the Darlington Creamery, I visited Darlington, Middletown township, and arranged with the man to board away from the Creamery and remain away during the entire period of quarantine. The personal clothing and the body of the man were properly disinfected before allowing him to move to his new quarters.

ASTON TOWNSHIP.

Dr. Robt. S. Maison, C. M. I. On receipt of a request from Aston (First-class township) Board of Health for advice in regard to handling a case of scarlet fever in the township, in which case the mother refused to keep the child isolated, and as to their best method of procedure in securing a physician and as to methods

for the support of the family in case of absolute quarantine, Dr. Maison took up the matter with the Board and the following advice from this Department was issued:—

"Replying to your letter of the 4th inst., concerning the conditions existing in Aston township, I would say that since the Board of Health in first-class townships has the same power as Boards of Health in boroughs and third-class cities, it is perfectly proper that they should have the physician for their Board visit the family, make the diagnosis and prescribe the precautionary measures that are to be carried out by the family and who is allowed to leave the premises, and if they are unwilling to observe such precautions it will be necessary to establish absolute quarantine and guards to enforce its provisions—such guards to be paid by the Board. An Order of Relief should however be issued, which provides for medical attention and the necessaries of life, as stipulated in the Act of May 7, 1907, a copy of which is enclosed. If requested, you are authorized by this Department to visit the case in question and assist in diagnosis."

GLEN MILLS.

November 1st, on receipt of information from Health Officer Speakman that scarlet fever existed on the dairy farm of J. M———, Glenn Mills, Thornbury township, I made an inspection and found that they ship 45 quarts of milk to a milk dealer named E. W. W———, 4709 Lancaster Ave., Via. P. R. R. house, no milk brought to the house except that used for the family and that all scalding and cooling of the cans was done at the spring house and every precaution was being used."

WILLIAMSON SCHOOL.

On receipt of information from the Commissioner of Health that a patient, O. H———, ill with scarlet fever, had been taken from the Williamson School at his home, No. 937 North 50th Street, Philadelphia, a special investigation was begun, developing the following information:

This boy on the 13th of March had reported to the nurse in charge of the Infirmary that he had a sore throat and had been given by her some local application. On the 14th he was allowed to go home and on the 15th his family physician in Philadelphia reported the case to the local Board of Health as one of scarlet fever. The Superintendent of the school knew nothing of the child's symptoms and had no idea that the child was suffering from scarlet fever. The particular cottage in the school in which the boy lived was quarantined, disinfected and a systematic examination of the pupils in this cottage and other cottages, where exposure placed its inmates under suspicion was begun by the nurse and the school physician. A distinct

understanding was had with the Superintendent that on the slightest symptoms of scarlet fever the boys would be isolated in the Infirmary, with the result that what promised to be the beginning of an epidemic was stamped out in a very short time.

"I investigated conditions existing at Ronco, German township, as reported by Dr. J. J. Mechem, yesterday (October 18). Health Officer Geo. Jacobs and Dr. Mechem accompanied me. I found conditions worse than reported by the doctor. Mr. Jacobs the Health Officer has certainly done his part, as he spent over one week having the town cleaned and drained properly, besides disinfecting a number of houses as well as the school house, the latter was under my instrctions, and the school board agreed to pay for all materials. The first home I visited was H. W———, the house was disinfected last week for typhoid fever. Five of the family are in the hospital suffering with the disease, the first boy affected with the disease was at home supposed to be well, his only nurse a sister seven years old. I found this boy in bed with a relapse seriously sick. I ordered the house placarded again. My next visit was to an adjoining house, No. 166. I found a bad case of scarlet fever and two children desquamating. I ordered a quarantine with strict observation. I next visited No. 153, the home of J. C——— and found a case of typhoid. This house I placarded. These were all the new cases found. I also visited No. 203, L. F———, suffering with diphtheria, No. 13, F. P———, one child with scarlet fever, one child with diphtheria, the home of L. J———, No. 190, three children with scarlet fever. These homes were under quarantine.

From very conclusive evidence many cases have existed that were not reported and in this way many have been exposed to diphtheria and scarlet fever. I established quarantine and the Health Officer who seems to be doing all possible, will keep in close touch with conditions. If the spread continues the school and church will be closed, but these conditions can be checked if every one will do their part. The Superintendent of the works has been faithful in cleaning the whole town. He has had a big squad of men cleaning and disinfecting under the supervision of the Health Officer, for ten days, so I don't see what can be done further at this time. If the disease continues to spread I would suggest a guard."

"P. S.—The Health Officer informs me by 'phone that the families quarantined for scarlet fever refuse to keep their children in the house. Would it be too severe to place a guard over these families? It seems impossible to keep them in check. It is a coal town and thickly populated."

Telegram—"Place guards scarlet fever, Ronco." Sam'l G. Dixon.

LACKAWANNA COUNTY.

Blakely. Dr. J. C. Reifsnyder, C. M. I. "Pursuant to instructions from the Chief Medical Inspector, I met the Board of Health at Blakely by invitation, on Sunday morning, April 12th, and discussed with them the outbreak of scarlet fever in the borough of Blakely. This outbreak was easily traced to the house of H. M———, and it, in turn, to an infected house in Priceburg.

The high water mark of the epidemic was reached on the 6th of April when 11 cases were reported.

It was evident in this meeting that the call upon the Department for assistance was more for the purpose of obtaining your approval of what is being done by their Board than for the reason that any particular need existed. Their Board seemed to be doing everything that was necessary and are active.

The points taken up were quarantine—absolute quarantine was being enforced and so far no need for assistance was found. The Board are perfectly conversant with the fact that pecuniary relief must come from the same source as any other case of borough poverty. I suggested that wage earners be given permits under suitable restrictions.

Disinfection—they were using the system of evaporating formaldehyde by artificial heat. My suggestion was that they adopt the Department's method by using potassium permanganate with formaldehyde in the proper proportions.

The schools and churches had been ordered closed and it had already been determined that they should be kept closed so long as necessity existed.

I suggested that the teachers make a list of absentees for the last ten days before closing the schools and that special inspection be made in every family in which an absentee was noted, and that books found in the hands of any child with the disease should be burned.

Milk—Orders had already been issued to discontinue the sale of milk from infected dairies, against the serving of milk in bottles, and requiring consumers to furnish receptacles at the door. Suggestions were made as to tracing the possible source of infection in conjunction with the milk routes.

Doctors were found to be very careless in reporting to their local Board. I strongly urged action in one flagrant violation on the part of a physician, discussed at this meeting.

Subsequent to this meeting arrangements were made for joint action with the Board of Health and School Board to determine the time for reopening the schools."

LANCASTER COUNTY.

Dr. J. L. Mowery, C. M. I. "Complaint having reached me that scarlet fever was present in the Pleasant Hill School, West Donegal township, a special investigation was begun on the 7th of October. Four children were found attending school in various stages of desquamation. The infected pupils were suspended and reported to the Health Officer for quarantine.

On the same day, having received reports of scarlet fever in East Hempfield township, I visited ——— school and found one case of pronounced scarlet fever, quarantined one typical case not reported who was being attended by Dr. R——— of Mt. Joy, two of the children in the family attending school and no precautionary measures being taken. In this district I also found several families having illness among their children accompanied by rash of a very evanescent type in which it was impossible to determine the diagnosis. The usual modified quarantine was established in each instance. The schools were closed and disinfected. I would respectfully recommend that action be taken against the delinquent.

LEHIGH COUNTY.

Summit Lawn School (Salisburg township). Dr. M. F. Cawley, C. M. I. "I was notified by Health Officer Brown that, at the Summit Lawn School in Salisbury township, a child became sick during the session and vomited in the school room, and that it undoubtedly had scarlatina. This is the school in which the epidemic occurred which is just about over and in which four deaths occurred. The first case in school began in this way and the whole school was infected so that out of about 45 pupils only 10 remained for a long time. There are 14 attending now. This report was a false alarm as the child had had the disease four years ago. I made the inspection yesterday morning and report at length because it might seem as not having been necessary."

POTTER COUNTY.

Austin. Dr. E. H. Ashcraft, C. M. I. April 21st. "In response to telegraphic orders an inspection was made in Austin with reference to scarlet fever, which was not being well handled by the local Board of Health. Investigation showed that but five cases were present in the town and in one or two instances a dispute as to the diagnosis had led to neglect of quarantine measures—in one case the child of a laundryman in the house from which the agency was conducted—it was deemed wise to advise complete fumigation of the entire lower part of the house, and that all wrapped bundles of laundry be opened and disinfected at the same time; and that the father of the child

should have the usual antiseptic bath and have all his personal clothing disinfected and remain away from home during the remainder of the quarantine period. This was agreed to and was entirely satisfactory to all parties concerned."

MEASLES.

ALLEGHENY COUNTY.

Dr. S. M. Rinehart, C. M. I. On February 12, by order of the Department, inspection was made of the schools at Blythedale where an epidemic of measles had been reported. 34 children out of a total of 79 were out of school, on account of the disease. Dr. Rinehart reports as follows: "This is a mining community, made up almost altogether of foreigners. In this school of seventy-nine, there are only ten children of American parents. A good many cases of measles have occurred in this community that have never been reported, on account of the parents never having a physician for the children, so that it has spread very rapidly. At present, however, the doctors seem to be reporting the cases to the Health Officer, Mr. Jones, and I have no doubt the progress of the disease will be checked soon. I visited two or three of the cases that had not been reported and found them to be measles in a stage of convalescence, so that there can be no doubt about the nature of the epidemic. Most of those children at present in the school have had the disease by this time."

ARMSTRONG COUNTY.

Yatesboro. Dr. T. N. McKee, C. M. I. "At the request of the Health Officer and school authorities of Cowanshannock township, I visited Yatesboro November 12th and after going over the situation carefully with the Health Officer, Principal of the Schools and local physician, deemed it advisable, on account of number of cases of measles developing within the last few days, to order the school (4 rooms) in that district closed until the building had been thoroughly disinfected and the epidemic gotten under control."

"I am glad to report that the school authorities manifest a desire to co-operate with the Department in protecting the health of those under their care."

CLARION COUNTY.

Fairmount City. Dr. J. T. Rimer, C. M. I. On receipt of telegraphic orders, the schools of Fairmount City, consisting of three public school-rooms and one high school room, were closed on the 30th of March because of a general epidemic of measles in Red Bank township. Dr. C. E. Sayres, Health Officer, was especially deputized to

investigate the alleged cases in the district and found measles in active or declining stage in forty-four dwellings, totalling about one hundred cases. The school rooms were closed and disinfected. The children from the uninfected houses were readmitted.

As modified quarantine had been established about the same time in all of these houses, it became necessary to employ additional disinfectors in order to accomplish prompt release from quarantine and carry out the wishes of the Department.

TIOGA COUNTY.

Crooked Creek. Dr. S. P. Hakes, C. M. I. "I beg to report that today (February 1) I examined cases reported by Health Officer Howell, alleged to be measles, whom he states had no attending physician. I found one case at G. W———, Crooked Creek, and four cases in the family of J. N. L———, Crooked Creek, both families residing in Charleston township; two cases in W. C———'s family, Crooked Creek in Middlebury township. All these families had been visited by Dr. C. W. H———, of Wellsboro, and none had been reported to the Health Officer.

On communicating with the physician by telephone he very willingly consented to make report of any future cases he visits and consented to assist the Health Officer in locating any other cases that have no attending physician. He realizes that he did wrong and I think in the future he will do better."

LEHIGH COUNTY.

Slatedale. Dr. M. F. Cawley, C. M. I. "April 1st, having been notified by Health Officer Heintzleman of a number of unreported cases of measles at Slatedale and Reiningers School, Washington township, I visited seven families, examined twelve persons and reported eleven cases suffering from the disease. Two of the physicians in the vicinity were plainly violating the law and evidence is hereby submitted which seems to be sufficient to secure their conviction. I would respectfully recommend that proceedings be instituted against them at once."

BLUE CHURCH SCHOOL.

"January 15th I visited Blue Church School, in Upper Saucon township, near Coopersburg, and ordered the school closed for disinfection. Out of an enrollment of 50 pupils there were about one dozen left. All the others are now suffering with measles.

In nine families physicians had not been called and the cases had not been reported.

REXTOWN.

Rextown. March 24th. "I desire to report an inspection of Rextown and vicinity in Washington township on account of the existence of a number of cases of measles without any medical attendance. I visited four schools and nine families, examining in all a total of 15 persons, finding 12 of them having measles. In two instances I closed the schools for disinfection."

SLATEDALE.

Slatedale. December 26th. "I desire to report an inspection of schools for measles at Slatedale, today. Fourteen cases—seventeen persons examined. Found the teachers in Slatedale were admitting children from houses placarded for measles."

DIPHTHERIA.

CUMBERLAND COUNTY.

Carlisle. Dr. H. B. Bashore, C. M. I. "I beg to report that I visited Carlisle, August 13th, on account of sale of milk and butter from H——— house in North Middletown township, placarded for diphtheria. I found that the patient had died a short time before my arrival and that there would be no sale of milk or butter until after disinfection. I gave instructions for a private funeral to be held within thirty-six hours. As this is the second death from diphtheria the last month in the county, it looks to me as though some of our physicians are afraid to use antitoxin sufficiently early."

LEHIGH COUNTY.

Dr. M. F. Cawley, C. M. I. On receipt of information that diphtheria was prevalent in the Children's Home, an asylum for orphan children, having a population of 35 inmates, located in Salisbury township, investigation was made on the 14th of May and developing the fast that the attending physician had not diagnosed the earliest cases as diphtheria and it was only when the child of the Superintendent sickened with the disease and Dr. S——— of Bethlehem was called that the disease was properly diagnosed. All of the children with a history of sore throat were isolated from those who were well, given curative doses of antitoxin and the usual regulations of the Department were instituted. All inmates who were exposed to the infection were given immunizing doses of antitoxin with the result that no further spread of the disease occurred. The total number of cases contracting the disease were six of the orphan children and the one child of the Superintendent.

WHOOPING COUGH.

LANCASTER COUNTY.

Western School, Earl township. Dr. J. L. Mowery, C. M. I. "On receipt of information October 6th that Whoopingcough existed in the Western School, I made a special investigation and found three cases of well developed Whoopingcough and three somewhat in doubt and in whom I think the disease is developing, in attendance at school. The school was closed to be disinfected and the regulations of the Department enforced with regard to school exclusion."

BROWNSTOWN & TALMAGE SCHOOLS, WEST EARL TOWNSHIP.

Brownstown and Talmage Schools, West Earl township. "On the 12th of October I investigated the Brownstown and Talmage school districts in West Earl township, in which Whoopingcough was alleged to exist and found twelve cases in the school actually suffering from the disease. I ordered the school closed and disinfected and the children excluded for the usual time.

WEST EARL TOWNSHIP.

West Earl township. "On October 23rd, by appointment with the school board of West Earl township I visited with a representative of their Board two schools for the purpose of determining whether or not whoopingcough existed. We took up the cases in these schools and found whoopingcough in each. The Directors wish to eliminate as much as possible all communicable diseases from the schools under their care and willing to co-operate with the work of the Department in every way."

PROSPECT SCHOOL, EAST DRUMORE TOWNSHIP.

Prosepect School, East Drumore township. "On receipt of information from the teacher at Prospect School in East Drumore township, on October 21st, that Whoopingcough existed among his pupils, I made a special investigation and found a number of cases in the school, ordered the schools closed and disinfected and infected children dismissed.

On the same day, with Dr. Heller, we completed our investigation at Brownstown where whoopingcough was alleged to exist in the village and succeeded in finding 49 cases. In each instance the regulations of the Department were enforced."

LEHIGH COUNTY.

Hartzel's School (Upper Milford township). Dr. M. F. Cawley, C. M. I. "I made an inspection today at Hartzel's School in Upper Milford township on account of alleged cases of whoopingcough.

I visited two families and the school, and while it is quite probable that whoopingcough is developing it has not reached the stage at which I would feel justified in making the diagnosis. The people have promised me however that should cough become severe, or should whoopingcough be noted they would keep their children from school.

"I also visited Riegel's School in the same township for the same reason; these children have paroxysms, which, though I have not seen them, from the description given by the mothers, I would pronounce to be whoopingcough. I visited two families here and saw seven children.

"I visited these places because the Health Officer reported to me that people were complaining and that they were afraid of sending their children to school for fear of their contracting the disease."

TIOGA COUNTY.

Morris. Dr. S. P. Hakes, C. M. I. October 30th. "Last week complaint was made to me that children with pertussis were attending school at Morris, Pa., and requested me to correct the conditions. I am also enclosing a letter with complaints along the same lines and at the same time the Health Officer of that district called my attention to the matter. I have made an inspection and submit the following report:

"Morris is an unincorporated settlement of about 1,500 to 2,000 people, having a large tannery, some small coal mining interests and some agricultural interests, etc. They have a Township High School, with four rooms and four teachers and an attendance of from 160 to 170 pupils. I met Health Officer Vandergrift there and with him visited the school. We inspected all rooms and from the history given us by the teachers and pupils themselves, and by the physical examination which I made, I picked out about thirty pupils in whom I could safely make a diagnosis of pertussis."

"I made out the Forms M. S. No. 1 for the Health Officer and he did the placarding. I went over the matter with the school directors, and requested the President of the School Board to close the school until the rooms were disinfected. The Health Officer writes me this was done."

TYPHOID FEVER.

ADAMS COUNTY.

Dr. J. R. Dickson, C. M. I. On receipt of notice that typhoid fever was existing on the dairy farm of J. Mc——— in Straban township, special inspection was made and the following report submitted: "August 8th, 1908. The conditions are as follows:—Patient is isolated. No one connected with the milk, utensils or stock comes in contact with the patient, or goes into his room. No one coming in

contact with the patient, or who enters his room, comes in contact with the milk, utensils or stock, or with any one having such contact in charge. The cattle are watered from a well and from a stream. The well is at the edge of, but within the barnyard. The well floor is not impervious and excrementatious matter is deposited on it from the feet of the farm laborers. The well wall does not exclude surface drainage. The stream Rock Creek, receives the barnyard drainage at a point probably four hundred and fifty feet distant. The stream also receives about one hundred and fifty feet above the point of entrance of the barnyard drain, drainage from a spring. This spring drain passes through a small lot of ground, used, recently, as a hog pasture. Less than two hundred feet from the spring drain, on slightly elevated ground, sloping toward it, is located the water closet. It stands on the surface of the ground and is used regularly by not more than three people daily, throughout the year.

The spring is the source of water supply for the family and also supplies the cemented trough in the spring house with water, into which milk containers are placed. Water from this spring is used to wash the milk utensils, after previous boiling, it is claimed. The spring is distant from the drain carrying the barnyard waste about eighty feet, and at a lower level by probably two feet, but owing to artificial protection does not receive such waste except during a freshet which it is reported has not happened within two years. Water is obtained from the spring by pump, a wooden one, surrounded by a floor. Waste water from mouth of pump returns directly to spring by a wooden receiver."

BLAIR COUNTY.

Altoona. Dr. Jos. D. Findley, C. M. I. The Department through Dr. Findley investigated an outbreak of typhoid fever in the city of Altoona and was able to assist in tracing it pretty definitely to a dairy farm supplying a number of people with their milk. More than ——— families were taking milk from the dairy of one J. W———, where a careful inspection revealed the following conditions:—

"On May 2nd W———'s brother went to the Altoona Hospital and developed a mild case of typhoid. Nothing further occurred to attract attention until less than two weeks ago when we began to have some cases of typhoid in families that used W———'s milk. Almost all of these cases had been away from the city within three weeks and the Altoona authorities explained them on that ground. But a week ago last Sunday, August 16th, a girl working for W——— was removed to the hospital with symptoms of typhoid. As soon as we learned of it we went to W——— and told him that he could not handle any more milk at his own house and barn."

Since then he has kept his cows away from his own water supply and used the supply of a neighbor to water them and to scald his cans and has boiled all the water used on his own premises and washed his hands before milking.

As soon as knowledge of this serious condition reached the Department the following letter was addressed to the Secretary of the Board of Health:—

August 27, 1908.

Mr. Samuel B. Trees,
Sec. Board of Health,
Altoona, Pa.

My dear Sir:—We have your valued favor of the 26th of August at hand, and are pleased to learn that your board is so active in its endeavors to avoid the further spread of typhoid fever in your city.

While we presume that your board has taken up nearly all, if not all of the points which would occur to us in the control of this disease, we beg your indulgence for outlining a few of the points which occur to us as requiring attention and which may perhaps in some one instance prove of value to you.

Whenever typhoid fever becomes at all prevalent, we believe it is absolutely necessary that notices warning the public to boil all milk and water intended for domestic use for at least twenty minutes before using should be posted about town, especially in the affected neighborhoods. All premises where typhoid fever exists should be placarded. It is valuable in that the dairymen who may have routes in your town shall know where the disease exists and thereby may be able to carry out your instructions relative to the leaving of milk bottles. We presume that you have already given orders that no milk bottles should be left at or taken away from premises where typhoid fever exists. If this is not done through the interchange of milk in the bottles or perhaps by infection of the general milk supply, the milk may become a great factor in spreading this disease. Instead of leaving milk bottles, the families should provide a container into which dairymen may pour the milk without the necessity of handling the container.

Lime should be distributed to all homes where this disease exists, in order that the privy vaults may be thoroughly limed, which will materially assist in preventing the infection of disease by transmission through flies.

One or more visiting nurses should be employed to go from house to house, instructing those having care of the sick, where a trained nurse is not in attendance, in the proper method of disinfecting the discharges and caring for the patient in order that secondary cases may be limited.

We have taken the liberty of sending to Dr. Findley, to be used in this emergency, typhoid circulars and as many placards.

A copy of the report from our laboratory relative to the examination of water specimens and milk sent to the laboratory lies before us, and while we fail to note that these reports show pollution by sewage, we would deem it advisable that your board have other examinations made of the general water supply used by the families now afflicted or wells which may exist in their neighborhood and of the

milk suspected, as well as the wells located on the premises from which the milk is taken. For this purpose we are having sent to you a box of bottles for the collection of water specimen samples.

Assuring you that we shall be pleased to advise you with regard to any troublesome conditions which may arise, and trusting that this outbreak may be speedily suppressed, I remain,

Yours very truly,

SAMUEL G. DIXON,
Commission of Health.

This letter was pulished in all of the daily papers of Altoona.

The Board of Health of Altoona having definitely determined that the milk supply was at fault, had it discontinued. A campaign of education was waged with householders so that all reasonable precautions were taken throughout the city to protect the well from those already sick, and the epidemic quickly subsided.

Such epidemics show us the very great importance of having every case of typhoid fever on dairy farms reported at the earliest possible moment, and impress upon us the importance of keeping such farms in first-class sanitary condition.

BRADFORD COUNTY.

Dr. S. M. Woodburn, C. M. I. Many investigations were made of typhoid fever on dairy farms, and the regulations of the Department enforced in all cases where laxity was found in their observance.

CAMBRIA COUNTY.

Hastings. Dr. W. E. Matthews, C. M. I. In July, 1908, the Department was called upon to render assistance to the borough of Hastings, where an epidemic of typhoid fever developed. The County Medical Inspector, Mr. R. E. Irwin, of the Engineering Division and Miss O'Halloran of the Nursing Staff, were detailed to study the situation and render all assistance possible to the borough Board of Health. A careful study of the water supply and milk supply of this borough pointed pretty conclusively to a polluted water supply as the direct cause of the epidemic. A sanitary survey showed the entire town to be filled with nuisances and gross pollutions of all sorts were readily found.

At joint meetings of the borough Board of Health and Borough Council it was decided to raise funds for enforcing the abatement of nuisances, for the equipping of an emergency hospital and for such other sanitary measures as might be deemed necessary in stamping out the epidemic. Work was at once begun under the general supervision of the borough Board of Health and Dr. Matthews; notices were served on all property owners to abate nuisances within 24 or 48 hours; lime wagons distributed disinfecting agents to every house

in which fever existed and to every house where nuisances were reported; full and overflowing privy vaults were emptied by an organized corps who distributed the contents on a farm at a distant point from the town and where it was plowed under each night; the town was placarded with warning signs; an educational campaign was begun to induce every one to boil all drinking water; the Nursing Corps, by house to house visit and by means of the emergency hospital, conducted an aggressive campaign for carefully disinfecting all excreta, and bed and body linen; and the Water Company began systematic efforts to prevent surface drainage entering the springs supplying reservoirs, building water-tight wells, condemning polluted privated water supplies and conducting a general sanitary campaign.

The Engineering Division secured 240 samples of milk and water for laboratory study, made special search for pollution on all premises infected with typhoid fever and aided the borough in supervising the disinfection of all open sewers; assisted with disinfection of the water supplies and with the cleansing and flushing of the water mains.

A total of 58 cases were reported as having typhoid fever, or were found by making a house to house canvass. Three secondary cases developed in the interval while the work was being prosecuted.

The suspicion that the water supply was the source of the outbreak was confirmed by detailed study of the milk and water samples sent to the laboratory.

The Pennsylvania Railroad, during the height of the trouble, while the wells were being repaired and water supplies disinfected, gave the borough, gratuitously, 6,000 gallons of pure water each day, from one of their tank cars.

An emergency hospital was opened by renting a seven-room house and placing it under the charge of Miss O'Halloran and a corps of nurses.

CAMBRIA COUNTY.

Richland township. Dr. W. E. Matthews, C. M. I. The following correspondence indicates the activity of the Health Department in other parts of Cambria county:—

"Yesterday (September 14), I received notice that a case of typhoid fever existed in the home of H. H ——, Richland township. I at once made an investigation and found a little girl suffering from typhoid fever. Mr. H——— conducts a dairy farm, supplying milk to the greater part of the borough of Windber. We went over the situation very fully with Mr. H——— and arranged to have the cows removed at once to the adjoining premises and for the disinfecting

and cleaning up of the premises in general. The water supply is from two springs; one has not been used for some time except for watering the cattle. When the water was low in the spring used for drinking purposes they began drinking the water from the spring used for the cattle. Two weeks following this the little girl developed typhoid fever. From the history of the case it seems about the only source from which the child could have contracted the disease. This spring is located very near a public road and the water being cold many travelers would stop and drink from it. Until we can determine positively that this is the source of infection I nailed the spring shut placing a warning sign on the same. I also sent to Dr. Herbert Fox, last evening, samples of water from each spring."

CAMERON COUNTY.

Emporium. Dr. H. S. Falk, C. M. I. In the early part of November an unusual prevalence of typhoid fever was noted in the borough of Emporium, and the good offices of the Department were solicited toward helping to determine the source of infection and to help stamp out the disease.

With the assistance of the Laboratory Division, 16 samples of water were examined bacteriologically, from the various intakes, reservoirs and spigots of the borough and from wells, and four samples were examined from a dairy farm supplying a good part of this borough with milk. These studies, together with an analysis of the cases in the borough, pointed conclusively toward the water supply as the source of the infection, and pointed especially toward the West Creek Reservoir of the Emporium Water Company.

Among those who contracted the disease and lost their lives in the early part of the epidemic was the young man who ran the pumping station supplying this reservoir with water.

During the course of this outbreak the people of the borough were assisted for a time by Miss O'Halloran, the nurse usually detailed for this kind of epidemic work, and from her notes it appears that 16 families were afflicted with typhoid fever. Of this number, at the time of her arrival, 7 had trained nurses—the remaining 9 families were assisted in every way by having the visiting nurse see the patients once or twice a day, and, in some cases requiring a great deal of attention frequent visits were made. Families were taught to care for the bed and body linen of the patient and were given instructions as to the proper disposal of the excreta, the care of dishes, and practical instructions as to the ventilation of the rooms.

One patient was found living in a miserable shanty on the side of a mountain, being nursed in a small room, used as a kitchen and general living room for a family of seven. Miss O'Halloran succeeded in getting the consent of the father of the patient to have him enter

a hospital. Arrangements were made by which he was removed in an ambulance to the railway station, thence to the Ridgway Hospital, where suitable care was given. The house was then disinfected by the Health Officer and cleaned up in the usual fashion.

The work of the nursing corps, together with the aggressive campaign waged by the local Board of Health, stamped out the disease during the month, and no new cases were reported for a period of two weeks prior to the nurses leaving.

CARBON COUNTY.

Bowmans and Hazards. J. K. Henry, C. M. I. "On receipt of information that an epidemic of typhoid fever was impending at Bowmans and Hazards an inspection was made at once. Dr. J. K. Henry and Health Officer H. N. Blunt met me at Bowmans on the 9th of September. Their study of the existing cases of typhoid and conditions in the community led to an immediate inspection of certain dairy farms in Lizard Creek Valley, East Penn township. The first farm, that of Mrs. O. S——— was in a sanitary condition and gave no history of contagious or infectious disease in its buildings for several years. The second farm, that of A. S——— No. 1, was in good sanitary condition, but two cases of typhoid fever had recently been treated in the farm dwelling. The water supply for this farm house is secured on the adjoining farm of A. S——— No. 2. The sanitary inspection of the last named farm showed stabling conditions to be satisfactory, no milk was sold, but the spring from which the water supply for both farms is secured in insufficeiently protected. A history was elicited of a possible pollution by the wallowing of animals in the spring and by surface drainage. The milk from the farm of A. S——— No. 1 was not retailed by A. S——— but was sold at wholesale to Mrs. O. S——— and retailed by her with product from her own dairy, with the residents of Bowmans and Hazards.

A history of 12 cases of typhoid fever was elicited in the occupants of the house and farm of A. S——— No. 2. All cases of typhoid in Bowmans and Hazards secured their milk supply from the retail delivery of Mrs. O. S———.

It looks at this time as if the water of the spring of A. S——— No. 2 is the source of trouble and that A. S——— No. 1 in securing the water supply for his family and dairy in this spring has infected not only his family but also his milk and that this milk has been the source of infection along the dairy route of Mrs. O. S———. In all about 15 cases of typhoid are present in Hazards and four in Bowmans. An order was issued to Mrs. O. S——— to discontinue the sale of milk for a few days until bacteriologic studies had been completed.

Samples of water from the spring were sent to the laboratory, the spring was disinfected and sufficiently protected to prevent the same sources of pollution occurring again.

CHESTER COUNTY.

Spring City and Royersford. On receipt of information from two citizens of Spring City, one of whom enclosed a clipping from a local paper, giving us information that typhoid fever was unduly prevalent in Royersford and Spring City, the Department assigned County Medical Inspectors, Joseph Scattergood and H. H. Whitcomb, to take up with the borough Boards of Health the details of the outbreaks, and the Engineering Division detailed Messrs. W. W. Ritter and Ira F. Ziegler to visit these boroughs and study their water supply and examine carefully the sewage disposal methods on each property where disease was said to exist, and within twenty-four hours special nurses were detailed to report in both towns for the purpose of making a house to house canvass and establishing a system of training the nurses and care takers in proper methods for the disposal of excreta and methods for general care of those having typhoid fever.

The first reports submitted by Dr. Scattergood convinced us that at least eighty cases of typhoid fever were then under treatment in Spring City and vicinity and that of those ill a large proportion of them were using the Spring City public water supply and that a goodly number were using water from dip wells.

The first preliminary study made of the outbreak convinced us that the water in good part was responsible for the outbreak of the disease. As soon as these facts reached us the following letter was addressed to Dr. J. C. Mewhinney, Secretary of the Spring City Board of Health and a duplicate letter was sent to Mr. C. O. Grander, Secretary of the Board of Health of Royersford:—

August 22, 1908.

Dear Sir:—The reports sent to us by our County Medical Inspector and by citizens of your borough bring to our attention the fact that your Board has to deal with a typhoid epidemic.

The following points are brought to your attention.

In handling of any epidemic of typhoid fever there are a number of things which assume a considerable importance and I desire to bring these matters to your attention and would ask whether you have instituted any regulations along the lines indicated and if so, to what extent?

Especially in time of epidemics of any disease the physicians should be compelled to promptly report all cases either conclusively diagnosed or presenting the clinical symptoms of the disease in question. If physicians are negligent in the matter of reporting typhoid fever to your Board at the present time they should be arrested and fined in order that no case may be neglected and thereby allowed to become a focus for secondary infection.

All houses in which typhoid fever exists should be placarded with a penalty attached for the removal of such placards. Circulars setting forth the rules and regulations to be observed by nurses or attendants having the care of typhoid fever should be distributed in every household where the disease exists and for this purpose I am sending you under separate cover a number of the Department circulars on typhoid fever.

The Health Officer should placard the house and ascertain the conditions existing on the premises, character of the privy, cesspool or whatever means are used for the disposal of excreta and the needs of the family, reporting the same to your Board and a lime wagon should be started to distribute freshly burned unslacked lime to the houses where the owners or occupiers are unable to provide the same for their individual use, this lime to be used in the form of milk of lime for the disinfection of excreta and for use in all closets or privies. The work of the lime distibutor should be checked up by the district nurse, who should visit each home where typhoid fever exists and where they are unable to procure the services of a nurse, directing them as to the precautions to be observed and seeing that the instructions of the physician are carried out.

Wherever possible in indigent families the patient should be transferred to a hospital at once and the room and its contents thoroughly disinfected, together with the privies.

Warning placards should be posted in conspicuous places; preferably on telegraph poles, in saloons and in the street cars directing all people to boil their water and milk for at least thirty minutes prior to its use for domestic purposes.

The delivering of milk in milk bottles should be prohibited and all dairymen should be compelled to deliver their milk into an individual container supplied by the householder, this container not to be handled by the dairyman at all. Unless this precaution is taken due to the interchange of individual milk bottles or the infection of the general milk supply of the dairyman, the infection is very apt to be carried in this manner.

All proprietors of meat markets and of meat carts which go about the streets peddling meat should be compelled to have their meat so placed in their markets that the handlings of the same by customers should be prohibited and all those delivering meat from wagons should be instructed that the customers must not handle meat before purchase, that the rear curtain of their wagon should be closed and that sales should be from the front of the wagon. In other words, no meat should be handled by prospective customers.

If the municipal water supply is found to be at fault the mains should be repeatedly flushed, all dead ends bled and copper sulphate introduced into the reservoir or screening chambers in the proportion of one to a million, this addition to be kept up for at least ten days.

Our records show that your Board has been derelict in making reports, and we expect weekly reports to be sent this office promptly henceforth.

Yours truly,

SAMUEL G. DIXON.

A detailed report from Dr. Whitcomb, prepared on the 21st of August, led us to believe that the situation in Royersford was not so serious and that about 40 cases were ill with the disease in this borough. Further investigation showed that many of the patients were being well cared for by professional nurses.

Those detailed to study these outbreaks received little aid from the Board of Health records in Spring City. Physicians up to this time had not been reporting typhoid fever and no records had been kept in the office of the secretary.

In order to determine the location of all persons sick with the disease every physician in the two boroughs was communicated with and from them were secured fairly complete lists of all typhoid cases treated since July 1st, and all cases under treatment at the present time in which a diagnosis had already been established or in whom they had reason to suspect typhoid might be developing.

On the 22nd of August the nurses detailed for special investigation and instruction began a routine canvass resulting in their visiting, in the period of sixteen days, ninety-nine patients in the borough of Spring City and vicinity and forty-two in the borough of Royersford. In each instance nurses and care takers were taught by practical demonstration the precautionary measures to be observed regarding excreta, bed and body linen of the patient, etc.

Investigation on the part of the representatives of the Department showed gross violations of the law on the part of nearly all physicians practicing in Spring City and on the part of some of those practicing in Royersford. So flagrant were these violations that it was deemed wise by the Department to secure enough evidence to convict two of the physicians practicing in Spring City. Information was therefore secured by Dr. Scattergood, charging two of these physicians with failure to report forthwith communicable diseases, under the Act of June 18, 1895. Conviction was easily secured in each instance and on the 16th of September one of these physicians, after pleading guilty of the charge, was fined $25.00 and costs, amounting in the total to $52.56; and on the 28th of September the other physician was convicted and fined $25.00 and all costs save that of bringing witnesses from Harrisburg.

A careful study of the water and milk supplies—a total of 93 samples—showed positive indication of sewage pollution in the some of the water supply; and on the dairy of A. H———, showed a total of 12,500 colon in one cubic centimeter of the milk. A detailed study will be found in the report of the Engineering Division.

The following tables show the number of cases found to have suffered from the disease between the 1st of July and the end of the year. They are arranged in quinquennial age periods, by sex, and are classified by age and attending physicians. A total number of

129 cases occurred in Spring City, 49 in Royersford and 16 in East Vincent, Chester county. Three patients died in Spring city, 4 in Royersford and 2 in East Vincent township.

CLASSIFIED BY AGE.

1 to 5,	19	31 to 35,	8
6 to 10,	39	36 to 40,	13
11 to 15,	25	41 to 45,	1
16 to 20,	36	46 to 50,	3
21 to 25,	22	51 to 55,	1
26 to 30,	18	56 to 60,	4

BY SEX.

Male,	90
Female,	94

Note.—During the time covered by this outbreak, 15 cases were reported to this Department in the borough of Spring City and 7 cases in East Vincent township—a total of 22. There should have been reported during this time 124 cases in the borough and 16 in East Vincent township.

In Royersford during the same period of time 45 cases were reported to the local Board of Health in the borough and 4 cases in the adjoining rural districts; in other words Royersford the physicians supported the Board of Health and the Board of Health was active and alive to the interests of the people. In Spring City the physicians were careless and the Board of Health did nothing.

CHESTER COUNTY.

Dr. Jos. Scattergood, C. M. I. W. Bradford Township. An investigation was made October 12th of a small epidemic of typhoid fever in West Bradford township, on the dairy farm of I. L———, resulting in the enforcement of the regulations of the Department in regard to the care of the patients and the excreta and the transfer of the cows to a neighboring farm during the remainder of the illness.

SPRING CITY.

Considerable time was spent in investigating the epidemic of typhoid fever in Spring City (See special report of typhoid conditions in Royersford and its vicinity).

Gross violation of the Act of June 18, 1895, was easily proven against several physicians in the district who had wilfully neglected to report cases of typhoid fever, and some of the County Medical In-

CLARION CO., PA.
Typhoid Fever.

spector's efforts were expended in securing the evidence upon which the Department proceeded to secure conviction against the physician violating the law.

CLARION COUNTY.

Dr. J. T. Rimer, C. M. I. Fairmount City. On receipt of complaint August 14, from certain citizens of Fairmount City that the regulations of the Department were being violated in a tenement house on the banks of a small stream just outside of this village, Dr. J. T. Rimer made a special investigation and reported as follows:

I found an American family occupying half of the tenement house. They had one case of typhoid convalescent. They had carried out the doctor's instructions. In the end of the house next to the street, and next to the stream, lives an Italian family, with one case of typhoid convalescing, and four others with all the premonitory symptoms of typhoid. They were using the closet with a vault dug in the ground, and paid no attention to disinfection in any particular.

All waste and house sewage and excreta from the patient already ill with typhoid were being thrown into the stream or on the ground between the house and the stream.

I ordered 10 pounds of copperas and a half bushel of unslaked lime to each vault to be used every other day until thoroughly disinfected in the double closet. I ordered a trench dug on the upper end of the lot above the closets 3 feet deep, 1 foot wide and 3 feet long, had them put two inches of lime in the bottom, to receive their slops, and cover it with a board. I insisted that the weeds be cut from the banks of the little stream passing the house and that lime be thrown along the banks of the stream. I also ordered that the people along the street further down the stream to cut the weeds in front of their houses and put lime along its course. The constable was appointed as policeman to see that the family of Italians carry out their instructions with regard to the disinfection of excreta and the care of their slops, his appointment to continue for a short time, at $2.00 a day until they were sure that everything was thoroughly cleaned up, and that the instructions were being faithfully observed.

The well is underneath the kitchen part of the house from which both families have their water for cooking and drinking and all household purposes. They have been instructed to boil the water.

On receipt of the report from the Medical Inspector the following messages were telegraphed the towns of South Bethlehem and New Bethlehem and letters were written the secretaries of the Boards of Health of these boroughs advising them of the possible pollution so that warning messages might be issued to their people.

"J. B. Dobson,
New Bethlehem, Clarion Co., Pa.

Dr. Rimer, Clarion, reports possible pollution water supply. Would suggest warning people boil water. Letter."

(LETTER.)

"We confirm telegram of to-day noting the fact that we have been advised by our County Medical Inspector, Dr. J. T. Rimer, of Clarion, of the existence of cases of typhoid fever among Italians in Red Bank township, in which it is feared that pollution of the Citizens' Water Company supply may have resulted through carelessness in the management of cases on these premises.

"While Dr. Rimer personally supervised the abatement and disinfection of existing nuisances on the premises and placed a guard to see that our instructions were carried out, we are of course unable to state what harm may have occurred before the matter was brought to the attention of our representative and would suggest therefore that consumers of this water supply be instructed to thoroughly boil it before using for drinking purposes."

Dr. J. T. Rimer, C. M. I. Rimersburg. The aid of the Department was invoked, July 20, in caring for certain cases of typhoid fever near the borough of Rimersburg in Toby township. In this particular outbreak among Italian miners, the first cases were reported in a house on top of the hill, and subsequently a series of cases in homes further down the slope. Inasmuch as these houses have been seats of former outbreaks it was deemed wise to have an investigation and the bacterial content of waters from the spring supplying this community tested in our laboratory. Notices were posted urging the boiling of all water used for domestic purposes, from these springs, and the usual precautions of the Department were enforced with regard to the disinfection of the excreta. The laboratory report showed no evidence of sewage pollution.

CUMBERLAND COUNTY.

Dr. H. B. Bashore, C. M. I. S. Newton Township. "I beg to report that I visited the home of H. B. in S. Newton Township, Conedoguinette watershed, September 5, on account of the presence of typhoid fever. I ordered every precaution to be taken in the disposal of discharges, and notified the Health Board at Carlisle of my action."

DELAWARE COUNTY.

Dr. Robt. S. Maison, C. M. I. Bromall. "On receipt of information, November 2, from Health Officer Field, I visited Broomall, on account of the existence of typhoid fever. The patient is a daughter of A. M., and has been under the care of Dr. J. G. Thomas, of Newtown Square for the past three weeks."

"There are 28 cows on this dairy with a daily output of 200 quarts of milk. It is sent to Philadelphia to a milk dealer named W. who lives at Llanerch. The milk dealer cleans all the cans and they are taken directly to the spring house which is 600 feet from the house and are chilled there. Those who come in contact with the sick have nothing to do with the milk. I can see no reason to apprehend any infection from the case of typhoid fever at this place."

BRANDYWINE SUMMIT.

"On receipt of information from Health Officer Speakman I visited Brandywine Summit on July 25, on account of butter being sold from a farm where typhoid fever existed. The patient, a child of I. B. was lying in the front room on the first floor with thousands of flies going from this room at meal time to light on the food in the dining room and kitchen adjoining. The butter is made in the cellar and the separator smelled mouldy. I ordered the patient's room to be properly screened and all dejecta to be disinfected. I also directed the Health Officer to visit the house in a few days to see if the orders had been carried out and, if not, to stop the sale of the butter."

HUNTINGDON COUNTY.

Dr. H. C. Frontz, C. M. I. Robertsdale. On receipt of a letter May 29, from A. E. Bachert, General Superintendent of the Rockhill Iron & Coal Company, Robertsdale, Pa., stating: "That there existed in Robertsdale a case of typhoid fever in the person of J. C., at the home of Mrs. P., and that the stools from this patient without being disinfected were being dumped into Trough Creek, which flows back of the house and through part of the town of Robertsdale, and that all the efforts of Dr. E. W. Black, the physician and himself, were of no avail toward correcting the condition." Dr. H. C. Frontz was detailed and reported as follows:

"I communicated by telephone with Health Officer of District No. 493 and directed him to go to the place and have the stools of this patient disposed of in accordance with the requirements of the Department of Health. He 'phoned me on the evening of June 1st that he had been to Robertsdale and that he did not believe the things would be corrected properly."

"A personal inspection was made, Mr. Bachert and Dr. Black accompanying me. I found the home of Mrs. P. in a very unsanitary condition. The stools were being dumped into a ditch about fifteen feet from Trough Creek. I found the privy located right on the bank of the creek and its contents could easily drain into it. The house belonged to the Rockhill Iron & Coal Co.

"I asked Mr. Bachert to remove the privy to a safe distance from the creek, and directed that a ditch be dug at least one hundred feet from the creek, in accordance with the instructions of the Department of Health, and that all stools be deposited in it and that lime be used as per regulations. These things I believe will now be done as Mr. Bachert is in position to see that my instructions are carried out, and is very willing to cooperate in the work."

"I endeavored to discover the source of this case of typhoid fever but could find no source other than that it might have developed from the drinking water which comes from the head-waters of Trough Creek which supply the Woodvale reservoir some distance above Robertsdale. As this water is being used by almost all the residents of Robertsdale I thought it wise to have a specimen of it examined, and so wrote you last night to send a bottle to Dr. F. W. Black, Robertsdale, for the purpose."

LACKAWANNA COUNTY.

Dr. J. C. Reifsnyder, C. M. I. Carbondale. On receipt of a letter from the Secretary of the Board of Health at Carbondale, August 21, 1908, relative to an outbreak of typhoid fever in that city, stating that 20 cases were then under treatment and that during three days of the week in which the letter was written 18 cases had been reported to their office, Dr. J. C. Reifsnyder was detailed to go over the conditions with them and special arrangements were made to make immediate inspection of every dairy supplying the city with milk. Permission was granted for a laboratory study of the water supply of the city, and Dr. Fox reported to their Board on the various samples, as follows:

No. 4 Pond: Bacteria per cubic centimeter, 420. Bac. Coli found in one cubic centimeter, 4.

Crystal Lake: Bacteria per cubic centimeter, 720. No. Bac. Coli.

Brownell Dam: Bacteria per cubic centimeter, 8. No Bac. Coli.

After receiving the report of the Medical Inspector and studying the letter of the Secretary of their Board to this office together with the laboratory reports of Dr. Fox, the following reply and advice was addressed to the Secretary:

"Mr. Fred W. Lewis,

Carbondale, Aug. 25.

Dear Sir:

Yours of recent date with regard to typhoid fever at that place is at hand and contents noted. From the reports it appears that water supply known as "No. 4 Pond" shows evidence of sewage pollution and we would strongly urge upon you to warn householders to boil this and other suspicious water supplies before using for drinking purposes.

If you will kindly advise us of the name and township location of dairymen from whose premises milk is marketed in your borough we will be glad to have them inspected at once. A representative of the Department has been detailed to make a sanitary survey of your watershed.

Very truly yours,"

Inspection of the dairies supplying milk to the city resulted in the finding of active typhoid fever on one farm, that of A. K. and, in convalescent typhoid fever on a neighboring farm, a full-fledged dairy, that of G. R. The regulations of the Department were enforced in each instance.

LANCASTER COUNTY.

Dr. J. L. Mowery, C. M. I. "On receipt of information that no report had been made of a case of typhoid fever existing on the farm of J. S., in East Earl township, near Goodville, a personal inspection was made and Dr. W. was found in attendance upon the patient, when I called. The doctor admitted that the patient had had typhoid fever since the 22nd of August and was unable to give any reason why he had not reported it to the Department. He told me he would report the case at once, and after I had defined the regulations of the Department to the family and arranged for the exclusion of one of the family to take care of the milk, I stated to the physician that I would report his derelict procedure to the Department to be considered by them. I might say that in searching for the source of infection, suspicion was plainly directed toward the small spring from which the house supply of water is drawn, coming underground by a pipe. Above this spring is a small watershed through which pours an open drain and near which are a number of surface closets. Under my direction the Health Officer will undertake to have these nuisances abated at once."

PENN TOWNSHIP.

"On receipt of information on the 22nd of September that milk was retailed to individuals from the premises of J. G., in Penn township, where typhoid existed, I made a personal inspection, and after being unable to make satisfactory arrangements to completely isolate some member of the family to continue handling the milk, I fixed upon the only remaining plan, viz: discontinued the sale of milk. I would say in connection with this case that the patient has been ill for a period of six weeks and was for the greater part of this time under the care of Dr. S. B., of Manheim, and that it was reported a few days ago at a time when it seemed as if the patient's life was in great jeopardy."

LEBANON COUNTY.

Dr. A. J. Riegel, C. M. I. Myerstown. On receipt of a letter June 24, from Mr. E. K., whose son was sick with typhoid fever, telling us that a number of cases had appeared in this town and in the adjoining country, a special investigation was ordered, and report from Dr. Riegel detailed a most disgraceful amount of pollution in the abandoned canal running parallel with Tulpehocken Creek, in the section of the town adjoining the properties of Mr. J. B. and A. Z., on both of which places slaughter houses were conducted with the filth from each handled in complete disregard of the health of the community, and giving rise to odors so abominable as to cause many complaints in the community and to furnish good cause to have our engineering division abate the nuisance at once.

About eight cases of the disease were specially investigated by Dr. Riegel without being able to find any one assignable cause as to the source of the infection.

POTTER COUNTY.

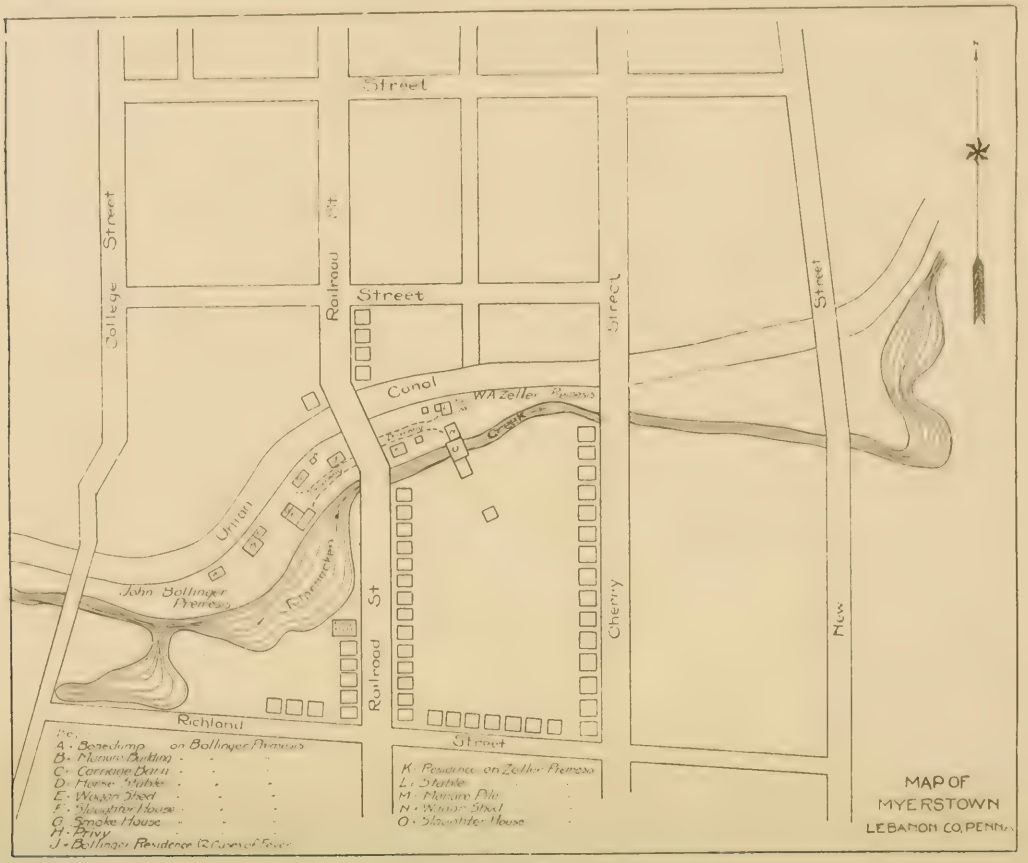
Lumber Camp. Dr. E. H. Ashcraft, C. M. I. "In accordance with your instructions of August 22, I made an inspection of the lumber camps on the Nine Mile on the 26th, where I found the following conditions:

"Two camps situated about 30 rods apart, one owned by Mr. F., of Roulette, this county, and one owned by Mr. C. C. R., of Coudersport, the former having a capacity of about 20 men, and the latter 30. Both are using water from the same spring properly piped to each building and apparently of excellent quality, and the spring not situated where likely to be contaminated.

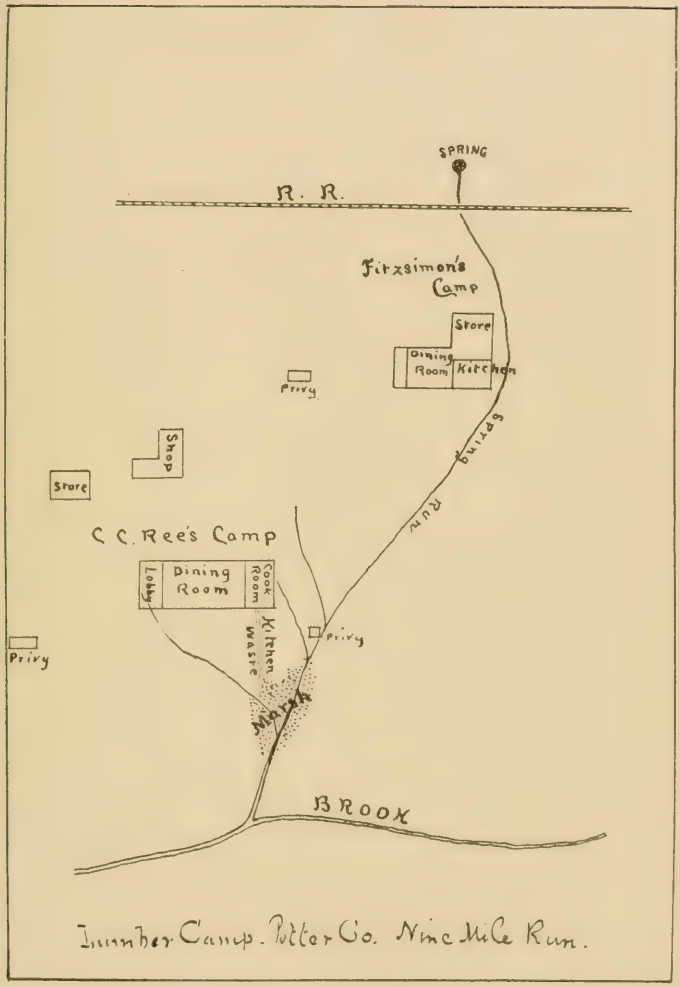
"The first two cases of typhoid fever occurred in Mr. F.'s camp. They were his own sons who were in the habit of spending their Sundays in their home in Roulette where, you will note, several cases of typhoid fever have been reported.

"Subsequently eight cases were contracted in the camp of C. C. R. None of the men in F.'s camp have contracted fever except those visiting Roulette. I found F.'s camp exceptionally clean and sanitary; all that could be expected under the circumstances, but the camp of C. C. R was the most insanitary of any camp I ever visited. There are about three small springs coming out near and under the camp with no ditch to convey the water away, and the hogs have a real heaven in the mire.

"But the worst feature of the camp is that a privy was placed over the spring run about 20 feet from the back door, and this privy was used by the first case in this camp. The water below the privy spreads out over the low ground which is also used as a dumping ground for kitchen refuse and among this rubbish there were numerous hog wallows.



Outbreak of Typhoid Fever.



Outbreak of Typhoid Fever.

"The surroundings furnish such a clear demonstration of the causative factors that I enclose you a rough sketch of the same, which will speak louder than words. It furnished such a good example of the means of contagion. I wish it could be spread broadcast throughout the State as an object lesson.

"These privies are infested with flies that go back and forth from the privy through the always open window to the dining room, alight upon the dishes, which are left, together with portions of food stuff, from one meal to another, and there perched upon these things they make their toilet, scraping off their germ laden legs on the food and dishes.

"The hogs wallow in the ooze flowing from the typhoid stools below the closet and then bask in the sunshine until their coats dry and they begin to itch, when they grunt and rub themselves on convenient stumps until the ground is literally reeking with germ laden dust. The men with their corked shoes track it in on the floor, and after the dishes have been washed and returned to the table the cook sweeps, a cloud of germ laden dust settles on the dishes and food, the men eat it with their food and wonder where they contracted typhoid fever.

"It is the old story. A previous case, flies, insanitary surroundings.

1st. I recommended that one of these closets be burned, and that the others be moved to a place which I designated, and log heaps be built over the vaults and a fire continued there for two days.

2nd. That a fence be built around a dry knoll a distance from the camp and the hogs removed to it and there confined.

3rd. All stagnant pools and wet ground be ditched, the weeds cut allowing the sunlight and air access to this wet ground.

4th. That the floors be flooded with a 1 to 1,000 Bichloride solution which I left.

5th. That slaked lime should be liberally scattered over such ground as I designated.

6th. That all empty cans and other garbage should be collected in a suitable receptacle and carried some distance from the camp and there burned periodically."

LEBANON COUNTY.

Dr. A. J. Riegel, C. M. I. Annville. "On receipt of information, August 13th, that a typhoid epidemic was impending in the town of Annville, special investigation with inspection of properties at the residence of eight of those who were ill showed no definite source of infection. In the course of the inspection attention was directed to the Reading Dairy Company's milk station, which furnishes milk and cream to many of the residents of Annville, and on a detailed inspec-

tion this building was found to be in a most insanitary condition. A full report of these findings was submitted by the Health Officer and this nuisance abated by order of the Engineering Division."

LUZERNE COUNTY.

Wilkes-Barre. Dr. Chas. H. Miner, C. M. I. In searching for a source of infection in cases of typhoid fever in the city of Wilkes-Barre late in August, information led to the inspection of certain dairy farms where typhoid fever was believed to exist. The dairy of R. showed a considerable number of cases along the route of his delivery. Inspection showed the farm to be in a very insanitary condition, but improvements were under way that would greatly remedy the conditions found. The water at this dairy was piped from the spring on a neighboring farm and on this neighbor's farm a case of typhoid fever was under treatment.

On the recommendation of Dr. Miner, County Medical Inspector, the Sanitary Committee stopped the delivery of milk from this dairy until such time as the possibility of infection had been definitely determined and sanitary conditions had been improved.

In all, a series of 24 cases developed in the families of those who had used this milk. Bacteriological examination of the water supply on the farm showed no sewage contamination. The bacterial content of the milk was high, however, and for a considerable time the milk of this dairy was refused by the Sanitary Committee of Wilkes-Barre. Conditions improved by the end of October and the services of the Department were no longer solicited.

SOMERSET COUNTY.

Boswell. Dr. Chas. P. Large, C. M. I. On receipt of information that typhoid fever was unusually prevalent in Boswell, Dr. Charles P. Large, Medical Inspector of the county was directed to confer with the officials operating the company supplying Boswell with water and to report upon conditions found. His investigations developed the fact that previous to December 15, 1907, the town of Boswell received its water supply from artesian wells; that about this date the pumps used in drawing this water from the wells were so damaged that the officials deemed it necessary to take their supply from Quemahoning Creek at a point in the stream below which a part of the sewage supply empties and near a point where slaughter house offal is received. This creek two miles further up received sewage from a mining town known as Jenner No. 2.

Shortly after this change of water supply was authorized typhoid fever developed and within sixty days from 150 to 160 persons were ill with this disease. It happened that previous to this change of

water supply the town had suffered from an epidemic of measles and la grippe and many of those suffering with enteric fever were convalescent from these diseases.

In Dr. Large's study of the situation samples of water were taken from the Creek at the intake above and below the point polluted with slaughter house offal and at the pumping station, and from three wells in the community, establishing the fact that colon bacilli were present in three samples taken from the creek.

After a conference with the authorities the artesian well supply was at once restored; notices were posted in public places advising that all water for drinking purposes be boiled and a campaign of education was instituted with such vigor that within a few weeks the disease was practically stamped out.

Eighteen deaths were reported in this epidemic and they may be justly charged to this unwise use of a visibly polluted water supply.

SUSQUEHANNA COUNTY.

Oakland.—Dr. H. B. Lathrop, C. M. I. On receipt of a petition signed by 80 citizens of the borough of Oakland and complaining of the insanitary conditions of the town and disregard of quarantine measures, special investigation was begun by Dr. H. B. Lathrop, who reports as follows, November 8th:

"In accordance with your instructions I visited Oakland, November 4th to investigate the conditions complained of in the petition which you forwarded to me and which I return herewith.

"I interviewed several of the petitioners and other citizens as to the cause of their complaint, called upon the Secretary of the Oakland Board of Health and found that a meeting of the board had been called for that evening. I was requested to meet with them and did so. At this meeting we discussed the management of communicable diseases, the regulations they have adopted and the individual cases complained of.

"Since October 1 there have been ten cases of communicable diseases reported to the Board: four of typhoid fever—no deaths—two of scarlet fever with one death and four of diphtheria with two deaths. At the present time there are in the borough three cases of typhoid fever, one of scarlet fever and one of diphtheria, all said to be convalescent. No new cases during the past ten days.

"From what I learned concerning these cases I concluded that quarantine had not originally been very strictly maintained.

"One of the cases particularly complained of was that of a child who was ill with scarlet fever in a boarding house where a number of workmen boarded. These men were allowed to come and go as

they wished. The physician in attendance and the Health Officer explain this by saying that the child was kept upstairs in a back room and that the men did not go near the patient or her nurse.

"I do not think that the rules of the Department as given in Circular No. 4 were strictly adhered to, and I suggested to them that in all such cases the rules as laid down should be observed to the letter or else the case placed in absolute quarantine. This child died, the house has been disinfected and no other cases have arisen from it.

"The Board of Health have adequate regulations and I think they are at present taking good care of their cases of communicable disease.

"Oakland is a borough of about 1,000 population on the opposite side of the Susquehanna River from Susquehanna borough. Most of the town is on a steep hillside. The town has an excellent water supply but is badly sewered. Only two streets have sewers and these do not extend very far. Consequently filth accumulates in some places until the rains wash it away. The cesspools and private drains should be looked after more thoroughly."

TIOGA COUNTY.

Mansfield. Dr. S. P. Hakes, C. M. I. "Yesterday (September 7) and to-day, I have been in Mansfield with the Borough Board of Health and the superintendent of the water works and on the water shed going over the matter of preventing the contamination of the water supply from the typhoid on said watershed.

"The superintendent of the water works sent workmen to the watershed and I have been there directing the placing of the typhoid fever premises in sanitary condition or so near that as possible. The outhouse that was located on the ravine close to the bank of Lambs Creek that was so objectionable because a patient had used it until taking to his bed, we removed to a safe place; and the contents were removed with a goodly amount of the surrounding earth, placed in a deep pit, and thoroughly covered with unslaked lime. We then filled the excavation with fresh earth well rounded up."

WASHINGTON COUNTY.

Morganza Home. Dr. C. B. Wood, C. M. I. "By order of the Chief Medical Inspector I visited the Morganza Reformed school on the 18th day of August and investigated an epidemic of typhoid fever reported in the institution, Health Officer Dr. Runion going with me. Dr. Johnson, the attending physician, had reported 20 cases of well developed enteric fever, eight or ten boys were under observation. We found the dairy barn, cattle and milk house all in excellent condition

and at the present time it looks as though the water supply is responsible for the outbreak. The source of water for all domestic purposes, excepting for drinking, is Chartiers Creek, at present a very small stream and not much better than a sewer. This creek water is pumped into reservoirs on the hill above the Home and is distributed throughout the buildings. The water used for drinking purposes is taken from two strong springs with perfectly clean surroundings and without visible evidence of pollution.

The superintendent of the Home has done all in his power to prevent the boys drinking water from taps but many do it in spite of his orders. Samples of the water from the creek, reservoir, the springs, and samples of milk were sent to the State Laboratory for bacteriologic study, and the water in the reservoir was, with the consent and advice of Mr. Snow, the Chief Engineer, treated by adding chlorine—eight parts to a million. Infection probably took place through the water used for domestic purposes drawn from Chartiers Creek.

With the observance of these precautions the epidemic subsided."

The laboratory studies confirmed the suspicion that the water supply was contaminated and also showed that the milk contained colon bacilli—this most probably reaching the milk through water used in washing and rinsing containers.

ACUTE ANTERIOR POLIOMYELITIS.

ADAMS COUNTY.

Gettysburg. Dr. J. R. Dickson, C. M. I. In July and August cases of cerebrospinal fever and acute anterior poliomyelitis were reported in the boroughs of Gettysburg, McSherrystown, McKnightstown, New Oxford, Cashtown and Fairfield. About the same time scattering cases of these diseases were reported in rural districts. With both diseases present in each community some confusion in diagnosis occurred.

On receipt of the following letter from Dr. G. H. S., of New Oxford, "You have, no doubt, heard that our vicinity is visited by an epidemic of cerebrospinal fever. The disease seems to be increasing, Gettysburg has a large number of cases. I have two in this town. The people are very much alarmed, and I do not wonder that they are. I have not been able to make a spinal puncture in my cases to demonstrate the germ, on account of the family objecting, but I consider my cases acute anterior poliomyelitis and should like very much to have these cases investigated so we could know better about the isolation, etc. I should be glad for any information you may be able to give me."

Dr. Dickson visited New Oxford and investigated these cases with Dr. S. and agreed with him that the patients were suffering from acute anterior poliomyelitis. They were not able to secure permission from the family to do lumbar puncture and thus to exclude positively by bacteriologic study the diagnosis of cerebrospinal fever.

Considerable anxiety was felt in several of the boroughs of the county. Special action was taken requiring the report of both anterior poliomyelitis and cerebrospinal fever by the borough Board of Health in Gettysburg.

REPORT OF DAIRY INSPECTIONS

1908.

DAIRY INSPECTIONS, 1908.

Total number of dairies inspected,	17,618
Number in a sanitary condition,	2,442
Number in an insanitary condition,	15,176
INSANITARY CONDITION OF COWS.	
Teats unclean,	451
Udders unclean,	487
Flanks unclean,	1,077
Tails unclean,	1,127
WATER SUPPLY FOR CATTLE.	
Water polluted,	499
Cattle can wade in water,	737
STABLE.	
Floor wet or unclean,	2,388
Ceilings unclean,	6,277
Ceilings not tight,	6,072
Manure not removed daily,	2,427
Cows can lie in their droppings,	5,806
Stable not well ventilated,	427
No sunlight,	2,165
COW YARD.	
Stable manure scattered so that the cattle can lie in it,	6,723
Pools of manure water in the yard,	1,586
MILK HOUSE.	
Not separate,	751
Doors and windows not screened against flies,	6,544
No provisions for hot water,	505
Milk utensils not clean,	134
Water supply polluted,	160
MILKING.	
Milkers do not wear clean coverings when milking,	10,314
Do not wash their hands before milking,	2,789
Teats and udders not washed,	7,768
Milking stools not clean,	1,889
Fore-milk not discarded,	9,972
Milk used on the hands and teats when milking,	3,609
HANDLING OF THE MILK.	
Milk not immediately cooled,	833
DISEASES.	
Typhoid Fever has existed within the last year,	61
Dysentery has existed within the last year,	8
Diarrheal conditions have existed within the last year,	5

DETAIL TABLE OF DAIRY INSPECTIONS, 1908.

	Insanitary Condition of Cows.				Water Supply For Cattle.		Stable.							Cow Yard.	
	Teats unclean.	Udders unclean.	Flanks unclean.	Tails unclean.	Water polluted.	Cattle can wade in water.	Floor wet or unclean.	Ceiling unclean.	Ceiling not tight.	Manure not removed daily.	Cows can lie in their droppings.	Stable not well ventilated.	No Sunlight.	Stable manure scattered so that the cattle can lie in it.	Pools of manure water in the yard.

Division of Laboratories and Experimental Station.

ALLEN J. SMITH, M. D., *Director of Pathology.*

HERBERT FOX, M. D., *Chief of Laboratories.*

OPERATIONS

OF THE

LABORATORIES AND EXPERIMENTAL STATION

FOR THE YEAR 1908.

The end of 1908 completes the second full year of the work of the Laboratories. During 1907 much was learned as to how the opportunities would be used. The physicians of the State quickly appreciated the advantage of the Laboratories and since the methods became known, they have been, with very few exceptions, willing, even anxious to comply with our regulations to obtain pathological data. The care with which material has been handled and shipped to us has been considerably greater in the past year than before and we have had to add but few names to our black list of men who sent specimens of infective material in a dangerous manner. We regret to report, however, that so far as data, direct requests and clinical helps from the doctors, are concerned, there has been little improvement. The service is delayed by this reason and time consuming correspondence required. We trust that this condition will improve as the applicants become more familiar with our work. Those doctors who received letters requesting further information have been very punctual in reply and satisfactory in answers.

The routine procedure of handling specimens has been the same as heretofore. This was described fully in our 1907 report and there has been no occasion or necessity for any material change. We have been more rigid in our requirements, during this year because some little confusion occurred over one or two examinations. No specimen is examined now without a request card properly filled out by the physician in charge. The water reports are checked off by both Dr. Rivas and the Chief of the Laboratories, thus making the facts doubly sure. Near the end of the year the Commissioner directed that the Laboratory reports should be used as a help to control the morbidity reports on Tuberculosis, Typhoid and Diphtheria, and any communicable disease whose infective agent should be discovered

8—17—1908

in feces examinations. Since that time, in accordance with this order, the Laboratory has made daily reports to the Division of Medical Inspection of the positive findings of that day's work.

During the year the Laboratory has received the following publications:

Bulletins of the United States Marine Hospital Service.

Bulletins of the United States Bureau of Animal Industry.

Thirty-fourth Annual Report of the Bureau of Animal Industry, 1907.

American Medical Directory.

Smull's Legislative Handbook.

Map of Pennsylvania.

The great increase of the work has required an augmentation of the staff in the position of diener of supplies. This man has charge of all outfits for the sending of specimens. The University has allowed us to use a large room in the basement which has been fitted up as a supply department. These outfits will be described under their repsective headings. The cages for small animals have been extended so that we now can accommodate several hundred. Two new microscopes have been purchased for the Laboratory. One is a Zeiss, fitted with apochromatic lenses and compensation oculars, and is intended for the finest work. It has already served for some observations upon the structure of the tubercule bacillus after the treatment in preparing our Product No. 5 according to the formula of the Commissioner. The other microscope is the latest improved Bausch and Lomb, with a lever micrometer screw and achromatic objectives. It is used for regular work on Sputum, Widals and the like. A large Arnold Steam Sterilizer was also purchased to meet the demands in the sterilization of sputum cans, and tubercle bacillus and water media.

EXAMINATIONS.

The number of examinations made during the year (9065) is tabulated in the accompanying chart. This is more than twice as many as were made during 1907. The greatest increases were made in sputum and water. The sputum takes the first place numerically (4735) because of the dispensary service in the various counties. The number of water analyses may be seen to rise gradually until August, then fall off until December when it took a great leap, due to the large number sent from Reading during the typhoid fever epidemic in that city. Widals have increased but little (11) during the year; August has the highest number until we come to December when the Reading epidemic again shows its effect. All the others increased over 1907 except the malaria blood examinations, which dropped off 23. The number of examinations for the successive months show an irregular but very definite rising course.

EXAMINATIONS DURING THE YEAR 1908.

1908.	A	B	C	D	E	F	G	H	J	K	Total.

E—Pathological fluid.
F—Pathological growth.
G—Milk and butter.
H—Water.
J—Feces.
K—Miscellaneous.

MALARIA.

During the year no positive malarial blood has been found. No noteworthy number have come from any one locality. The blood smears are usually extremely well made. It is to be regretted that the physicians give quinine first and then send the blood smears. It would do the patient no harm if the specimens were taken before the drug was exhibited. We might then find an explanation to the source of some unexplained chills or continued fevers.

WIDAL TEST.

The samples of blood for the Widal test have come from scattered districts except during the early year when they came principally from the Allegheny Valley and in December when Reading supplied the majority. They have only increased 11 over 1907 and the percentage of positive has risen three per cent., being 20.4 per cent. in 1907 and 23.7 per cent. in the past year. This can of course bear no relation to the established cases of Typhoid Fever. Fourteen (3.7 per cent.) samples have been unfit for examination, a thing which usually occurs because the paper is placed in the envelope before the blood is dry. Among the females the percentage of positive is 28.1, higher than that of the males which is 20.6.

The dry blood method, while convenient to collect and mail is not as accurate as the fluid serum technic. The Commissioner has approved a new type of outfit which is in the form of a spindle shaped glass bulb in which the blood is collected and allowed to coagulate. The serum when drawn out in the Laboratory is clear, and permits of accurate dilution. This will not be put in use until 1909.

SPUTUM.

The tests on the sputum have been confined entirely to the Tubercle Bacillus. Our methods of handling, staining and viewing the specimens have remained the same, whether the tubercle bacillus alone was considered or we were looking for some mixed infection at the physician's request. The number of specimens is nearly five and a half times as many as in 1907. It does not seem worth while to set down the percentages of positives and negatives of the two sexes, because many of our examinations are repeated upon specimens from the same patients, as many as five times in some instances; moreover, the information is sometimes not celar or intentionally misleading. It was related to one of the staff of the Laboratory that a physician had sent two specimens from the same patient under different names to see if any attention would be paid to the first examination. No attention is paid to the patient's name, it might be added here, this being merely a mark of identification for the physician. For the same reasons, figures upon occupation would not be accurate. While a percentage of positive cases cannot be statistically valuable, it might be well to mention that we expect an average of one in every three sputums to contain tubercle bacilli. This is, curiously enough, quite regular and while one day or week may run quite low, it will be balanced by a high percentage during the next similar period.

One thing can be said from our figures about the packing and condition of the specimens. In 1907, 6 per cent. of 869 specimens were unfit for examination, while in 1908 only 3 per cent. of 4,735 were unfit.

When specimens are sent by the physicians they should be marked 1st, 2nd, or more as the case may be. This is done regularly by the dispensary physicians, but should be done by all. If no tubercle bacilli have been found in the first two specimens, it is the practice of the laboratory to digest the tenacious mucus and centrifuge the fluid, the sediment being stained as the original sputum. This requires three days, a fact which should be borne in mind after sending the third specimen.

By reason of the enormous increase in this work, 2,000 more double tin mailing cases were purchased for this service. In some were placed the screw topped salve box, as heretofore, and in others, a new heavy shell vial containing about two cubic centimeters of 1-2000 bichloride of mercury solution and fitted with a pitch cork. These are intended for sputum only and are so marked.

At the beginning of the year a cage was erected over the desk at which the spreading and drying of the sputum is done. This cage consists of a glass plate supported on the sides and front by a wooden frame fitted with wire screen and slanted, so that it is two inches

higher at the back than at the front. At the back is a solid wooden partition from which a vent leads to a 6-inch galvanized iron pipe containing a large Bunsen flame to create a draught. All the dried particles go up this flue and are destroyed by the high temperature of the air or walls. The top of the shelter is hinged so that it can be lifted up out of the way. It is down while the operator is handling the specimens and while they are drying after being spread. When dry, they are rendered innocuous by fixation in the flame and the shelter is not used further. The device serves to protect all members of the laboratory staff but especially the worker who examines the sputum.

URINE.

These examinations have been greatly increased this year by reason of special examinations for the local dispensary. The Laboratory stands ready to examine any case for tubercle bacilli. The requests for diazo have been few (13). It is curious that more physicians do not avail themselves of the facility to gain one more fact to aid in the diagnosis of Thyphoid Fever.

PATHOLOGICAL FLUIDS.

These maintain the usual character. The requests and descriptions have been fuller and clearer than in former years. They increased but few over the previous year.

PATHOLOGICAL GROWTHS.

These specimens have been handled as described in our last report. They increased nearly fifty per cent. The descriptions are too meagre and many cards contain such words as "Don't know," giving no source, or hint of clinical conditions. The examination is in charge of Prof. Allen J. Smith. They comprise the usual kinds of material submitted to a pathological laboratory for diagnosis, principally taken by operation.

MILK.

These specimens have increased only 2. They are sent well for the most part. The senders are usually men who have direct interest in the character of the milk. The larger part have been to exclude the milk as the source of Typhoid infection. No butter has been examined. The method of examining the milk is the same as for water and the details given are the same unless special requests, such as leucocyte

count and streptococci, are made. The following is the tabulated list as to county, of towns from which milk has been sent. The figures indicate the number of samples from the respective places:

WATER.

The analyses of water come next to the sputum in number. They have increased about thirty per cent. The method of receiving, handling, labelling and examining the samples has remained essentially the same. Bacteriologist Rivas has made a few improvements in his method, which will be described further on.

The same type of bottle is still used; a ground stoppered flint glass bottle of 4 ounces capacity. To insure a tight fitting of these stoppers and necks, they are all numbered in the pairs as originally received from the manufacturers before they are put into service at all. Until the Autumn these bottles had been fitted with string by which they could be drawn from the water after filling. After consultation with the Chief Engineer this was abandoned and a muslin cover substituted. This cap is so cut that it can be tied over the stopper and neck far enough to protect the junction of the stopper and neck from contamination with dust or dirt from melted ice. A new tag form was also adopted containing spaces for the name of sender, source and time of collection. This last is extremely valuable, especially in the warmer part of the year, but is rarely given except by the Department's Inspectors.

During the year 1908 several improvements have been made in the bacteriological analysis of the water by Dr. Rivas, the most important of which is the differentiation of Bacillus coli communis from allied

species in water, in which by certain reactions and differential tests it has been possible to make a more exact diagnosis and to lesson by one-half the time required for the search of this micro-organism. The work is fully described in the 1907 Report and has been repeatedly verified. Dr. Rivas has also succeeded in elaborating a simpler method for the presumptive test for Bacillus coli communis in water, at present in print, a resume of which follows:

One cubic centimeter of the suspected water is plated on litmus lactose agar and inoculated at 37 degrees for 18-24 hours at the end of which time a number of the suspected pink colonies, resembling Bacillus coli communis, are inoculated on 1 per cent. dextrose fermentation tubes and kept at 37 degrees C. for 24-48 hours.

Based on the principle that Bacillus coli communis, due to an excess of lactic acid production in dextrose bouillon, does not show a complete exhaustion of the sugar in the medium, while allied species called "Saccharolytes," also fermenting dextrose, exhaust the sugar, tests for remaining sugar may be made after 48 hours and those showing its absence can be positively excluded as Bacillus coli.

The number of Bacillus coli communis by this method can be detemined with fair accuracy as follows:

Given the case that 1 cubic centimeter of water plated on litmus lactose ajar, twelve suspicious pink colonies are found and four inoculated on 1 per cent. dextrose fermentation tubes, from which two are found to ferment without exhausting the dextrose, it is assumed that such a water contains about six Bacillus coli communis per cubic centimeter, which can be proven by applying the other tests characteristic of this micro-organism.

By means of this method most of the difficulties of the old presumptive test methods have been eliminated and it has been possible for the laboratory to make a preliminary report of the suspected water 72 hours after it has been received for examination.

The importance of such a method is obvious. It gives not only a general idea as to the quality of the water, but it also predicts with a certain accuracy as to the degree of pollution if such should be found to exist, and what is more, the short time required for such preliminary research has proven to be an important factor in quickly locating polluted sources, thus greatly shortening the time in controlling epidemics due to contamination of the water supply. By the use of this test, the laboratory was able to assist the Division of Sanitary Engineering in the Reading Epidemic by showing in three days just where the pollution was.

The following is a list of places as to county from which water has been received. The figures opposite the names indicate the number of samples from the respective places.

FECES.

These have increased ten in number, 24 having some bearing upon Tuberculosis. Of this 24, six or 25 per cent. were found positive for the tubercle bacillus. This of course does not indicate such a fre-

quency of tuberculous enteritis, because many phthisical individuals are constantly excreting the organisms with the dejecta. The remaining sixteen have been sent for parasites, occult blood and Typhoid Fever. Only one in four of the last were found positive. The examination of feces for occult blood is difficult and misleading, because of the manifold sources of error. It has not been done by chemical tests; when such a request was made the report was made upon the microscopic findings.

MISCELLANEOUS.

The specimens classed under this heading consist of diphtheria culture and swabs almost entirely, with a few such specimens as gall stones, skin scrapings and wine from a communion cup, upon which our opinion was requested. Most of these unusual things have been satisfactorily examined. We were not able to discover any tubercle bacilli in the wine from a communion cup or from swabs made around the rim, although a phthisical person is said to have drunk from it but a few minutes before the specimens were taken. The examinations for diphtheria bacillus are made as formerly upon cultures or swabs sent or brought to us and report has been made frequently by telegraph at the request and expense of the physician.

RESEARCH WORK OF THE LABORATORY.

During the year the Laboratory has had the following subjects under investigation. Separate copies and reprints of published articles accompany this report.

1. First report on the products of the Tubercle bacillus and notes on efforts at producing immunity.
   Separate report.
   Work still in progress, discussion in text.
   Directed by Dr. Dixon.
2. First report on the Effect of Repeated Injections of Old Tuberculin into Healthy Cows.
   Reprint separate.
   Work still in progress, discussion in text,
   Directed by Dr. Dixon.
3. Note on Similarity of Barium Carbonate Poisoning and Rabies in Dogs.
   In progress.
   Directed by Dr. Dixon.
4. Note on the use of the Products of the Tubercle bacillus on Cows.
   In progress.
   Directed by Dr. Dixon.
5. Notes on the autopsy of Mock Sem, Leprosy and Tuberculosis, Dr. Allen J. Smith.

PRODUCTS OF THE TUBERCLE BACILLUS.

The first part of this experimental work is presented with this report. It was handed to the Commissioner during the Summer of 1908. The work has continued, our efforts being to find some method of administering the dose, which would give the highest resisting power to the experimental animals.

The text may be conveniently divided into subheadings as follows:

I. Dead Degreased Tubercle Bacilli.
   a. Injections before infecting with Tubercle bacilli.
   b. Tubercle bacilli first followed by injections of the degreased organisms.
   c. Effect of Sensitization by 2 doses at proper intervals upon subsequent injections of tubercle bacilli.

II. Tubercle Bacilli Toxin.
   a. Injections before infecting with tubercle bacilli.
   b. Tubercle bacilli first followed by injections of toxin.
   c. Effect of sensitization by 2 doses at proper intervals upon subsequent injections of tubercle bacilli.

III. Combined Effects and Special Experiments.
   a. Effect of alternate injections before Tubercle bacilli.
   b. Effect of alternate injections after Tubercle bacilli.
   c. Special work on Cows.

IV. Therapeutic use, syringes supplied to Department.

I. Dead Degreased Tubercle Bacilli.

a. Injections before infecting with Tubercle Bacilli. The later experimentation on this point has but confirmed our earlier work. There is no protective power developed in guinea pigs and rabbits by the repeated injections of a quantity, which will cause no consistent loss of weight. The following chart will show this better than notes.

No.	No. Inj.	Quantity.	T. Bc.	Length of life.	Weight change.	Post Mortem.
G. P. 204	23	.001 mg.	.5 mg.	29 d.	—150 gr.	Extensive diffuse caseous tuberculosis.
229	22	.001 mg.	.5 mg.	36 d.	—270 gr.	Same as 204.
232	22	.001 mg.	.5 mg.	30 d.	—30	Extensive caseous tuberculosis of liver, spleen and site of injection.
449 C.	0	0	.5 mg.	30 d.	—45 gr.	General diffuse caseous tuberculosis.
450 C.	0	0	.5 mg.	30 d.	—18 gr.	
Rabbit. 9	15	.05 mg.	2. mg.	61 d.	—375 gr.	General caseous infiltration of solid organs, nodular tuberculosis of glands and omentum; control had caseous pneumonia.
27 C.	0	0	2. mg.	38 d.		

Although these pigs had received weekly injections of a dose which did not cause loss of weight during the treatment, lasting over 5 months, there was no development of immunity. The rabbit lived longer than its control but the lesions were quite as advanced if not more so, because the pneumonic process shortened the life of the latter. These are the pigs reported in the separate report as having been treated a long time before injecting the organisms. They retained their weight for some time after infection and then rapidly went to pieces.

b. Tubercle bacilli first, followed by injections of the degreased organisms. The well known susceptibility of the guinea pig to the tubercle bacillus and the irregularity with which rabbits behave when infected has made it difficult to establish a proper dose to administer before proceeding with the therapeutic use of the product. It is considered wise to use a dose which will kill the controls in two or three months but occasionally this dose will be overcome or the infection may be so slow that the effect of the therapeutic injections becomes problematic. However, the results reported in the first article have been followed by others. A very large set of animals was injected with a minute quantity (about 1-30 mg.) and then weekly inoculations of No. 5 made in doses of .001 mg. One died after three injections and showed only a few miliary tubercles in the liver. Another died without lesion apparent microscopically, while a third showed a few miliary tubercles. Three are still living (about 8 months) and maintain their weights. In our report attention is drawn to the fact that while the life of the animal is not materially lengthened there is some change in the character of the lesions. This is well illustrated in one small experiment where the tubercle bacilli were introduced under the skin in fine emulsion. Two of the animals receiving doses of No. 5 therapeutically, developed caseous pneumonia while the control had miliary tuberculosis. This experimentation must eventually lead to something since all our experience is toward the modification of the process in intensity and rapidity of development. Many other sets are now under way. The regulation of bacterial dosage is most puzzling since the optimum dose cannot be expressed in definite terms.

c. Effects of Sensitization by 2 doses at proper intervals upon subsequent injection of tubercle bacilli. Although we have shown in our previous work that an injection of tubecle bacilli will not sensitive for a subsequent injection of No. 5 and that the reverse is likewise true, it was hoped that something might be learned if No. 5 were to be used on the same pig twice and tubercle bacilli given after the period of sensitization had passed. The result suggests that while anaphylaxis is not acutely shown, there must be some senitization because

the animals died with very active productive lesions, a little sooner than the controls. It seems that this is comparable to the results of attempts at active immunization described in the first paragraph, only perhaps more pronounced because of the larger does used.

II. Tubercle Bacillus Toxin No. 10.

a. Injections before infecting with tubecle bacilli. Attempts at establishing tolerance for the tubercle bacilli by injections of this material have met with the same results as heretofore and precisely to those with No. 5. They have been run along together, one set of pigs received 16 doses and another 18, but they died after the same average length of time as the controls. Rabbits are being continued and we are not ready to report on them.

b. Tubercle Bacilli injected first followed by the Tubercle toxin. This has had the same results as before, but we have not been able to lengthen the life of the animal to any material extent. The lesions seen in the animals differ from those of the set treated with dead degreased tubercle bacilli in that they are more limited in extent but show greater tendency to softening of the caseous material.

The following shows one set of animals which is being carried along with the hope that the living control will have more extensive lesions than the treated one. It shows well the irregularity of infection and how one can easily use less than the optimum dose. This work is being followed assiduously and should have good results.

No.	Quantity T. Bc.	No. inj. No. 10.	Quantity.	Life.	Weight change.	Post mortem.
312 C.	1-40 mg.	0	0	living		
313 C.	1-40 mg.	0	0	21 d.	—30 gr.	Few miliary tubercles in liver and spleen.
314	1-40 mg.	16	1. mg.	living	+195 gr.	
315	1-40 mg.	6	.1 mg.	60 d.	—105 gr.	Few miliary tubercles in spleen and liver, caseous tubercles on omentum.
316	1-40 mg.	1	.1 mg.	12 d.	—25 gr.	

c. Effect of Sensitization by two doses at proper intervals upon subsequent injections of tubercle bacilli. This experimentation has had the same results as described under Dead Degreased tubercle bacilli. The large doses necessary to produce the few symptoms of hypersusceptibility must have power of reducing the resistance to the tubercle bacillus. There have been no sudden deaths or hemor-

rhages in these tests. Injecting the tubercle bacillus into the animal first was done once with no appreciable difference in the pathologic experiments.

III. Combined Effects and Special Experiments.

a. Effect of alternate injections before tubercle bacilli. From this line of work much was hoped because the two products represent the principal constituents of the organisms, in what we think should be the easiest form for the tissues to combine with. Our expectations were not fulfilled however, because guinea pigs will not stand the alternate use of these products. When combined in one inpection the loss of weight is dangerously rapid even when using smaller doses than has been our rule. These experiments have therefore never reached the stage at which we could determine the effects of combined or alternate dosage.

b. Effect of alternate injections after the Tubercle bacilli. Of this work we can only report progress. The accident in our animal room prevented us from having animals far enough advanced to note their condition.

c. Special cow work. The accompanying chart illustrates the manner in which the work was carried out. A herd of cattle, consisting of three infected animals (No. 4 adult dry Holstein, No. 5 adult dry Red Pol, No. 6—14 month Jersey bull) 2 suspicions (No. 3 adult dry Holstein, No. 7—1 year Holstein heifer) and 2 healthy cows (No. 11 adult dry Jersey, No. 8—1 year Holstein heifer), was divided as per chart for straight dosage with 5 or 10 or for combined treatment, at first under the skin and latterly into the jugular vein. They are arranged as far as possible, to represent all phases of the work in immunization that we have tried on smaller animals. In order that the test might be severe and final we decided to put the tubercle bacilli into the vein. As a preparation for this, the last two injections were also made into the vein.

The courses of treatment consist of regular doses of No. 5 (2 cows) regular doses of No. 10 (1 cow) and alternating doses of Nos. 5 and 10 (3 cows) until the two intravenous injections when they are given together. A week after the last dose, the bovine tubercle bacilli were given. This was on the last day of 1908 and the experiment will not be completed for 3 or 4 months. It will be reported later separately. The immunizing injections lasted from June to December 1908.

No.	Condition.	Subcutaneous Injection.										Intravenous Injection.		T. Bc. Intravenously.

IV. Therapeutic use and Syringes Supplied to the Department.

We have continued to put up these experimental products in small syringes, each containing one dose diluted in one cubic centimeter of physiologic salt solution. The doses in use are as follows: Dead Degreased Tubercle Bacilli No. 5, .000001 gram, Tubercle Bacillus Toxin, .0.001 gram. This latter figure means that a quantity of the germ free filtrate equal to that weight of living tubercle bacilli is present in one cubic centimeter of the dilution in salt solution. All syringes are controlled for purity by animal inoculations. The syringes are sent to the Department at Harrisburg for distribution to Dispensaries or physicians competent to handle the toxin. A few private individuals have been supplied. The syringes filled, controlled and supplied by the Laboratory are as follows:

Department of Health Harrisburg.

No. 5—747, No. 10—901

State Sanatorium at Mont Alto.

No. 5.—545 No. 10.—480

Dr. W. C. Posey, Wills Eye Hospital, Phila.

No. 5—10 No. 10—10

2. Effect of Repeated Injections of Tuberculin into Healthy Cows.

Our first work, presented as a reprint in this report, has led us to continue the experiments and find out the fate of those minute areas of necrosis in the lymphatic organs. Their character and location, described in the first article, led us to speculate as to their probable relation to blood destruction and the various degenerations consequent upon choronic intoxications such as the repeated use of tuberculin would produce. To continue this, three new cows were obtained in the late Autumn and are now being injected every two weeks and will be so treated until 8 months have passed. They will then be killed and a thorough study of their organs made.

3. Note on the Similarity of Barium Carbonate Poisoning and Rabies in Dogs.

Since the United States Department of Agriculture recommended the use of Barium Carbonate as a poison for small rodents, many cases of so called Rabies have occurred around stables where it was

used. This line of experiments was started with the idea of calling attention to the course of symptoms produced by this chemical and to emphasize the differences from Rabies. We have been able to establish the picture of an acutely fatal dose of this drug and outline somewhat vaguely however, the effects of very minute repeated doses. If the toxic dose be given in a capsule the dog will either vomit the body undissolved or in pieces. At any rate the symptoms appear to a slight extent and then rapidly subside. If however, natural conditions be approached by giving the drug in milk or meat the course is quite regular. It has been found that a quantity of .2 or .3 gram will kill a dog of 12-15 pounds in eight to fourteen hours. A half starved dog will not always eat the full amount of food given and it seems that he knows the presence of the chemical. Stomach tube administration was not tried because we did not wish to induce vomiting. About three hours after the dose mentioned above, the dog will seem restless and whining and will probably vomit small quantities of fluid green material in which barium can be found. A little later he will be noticed to drink a small quantity very frequently. A green froth may be present around his lips and teeth. When he drinks there are no convulsive movements of head, jaws or neck. He will next start to tremble and lie on his side by preference. A looseness of the bowels occurs first about 4 hours after giving the poison. The passages have no special sign of recognition at this time, but later will be fluid green. Vomiting continues with considerable regularity every quarter hour and the vomitus has the same character. Thirst increases and the animal may consume a gallon in the last three or four hours that he is able to stand. Much is of course vomited. Urination is not frequent. In the urine barium has not been found, but in the stools, early in the course of the symptoms the tests are positive. About 5 hours after receiving .2 to .3 gram a palsy of the posterior extremities appears which rapidly progresses to paralysis. If this latter appear, the dog never recovers. The paralysis advances to the anterior extremities and neck in another hour and in 8 hours all the body is motionless except the eyes. In barium carbonate poisoning there is a notable slowing of the heart similar to the digitalis effect. It starts to decrease in frequency about the 5th hour and from then until just before death, will run down to 60 or 64. A few minutes before death, the pulse becomes rapid, thready and cannot be counted. The abdomen starts to swell about 3 hours before death. This is probably due to intestinal paralysis because the small gut is enormously distended and the peristaltic movements were absent in one dog killed a few minutes before death would naturally have ensued. The animal finally dies from respiratory failure.

During the course the animal will rarely eat. When non lethal doses have been given, he may take a little food after the critical height of his symptoms has passed. At no time is there any suggestion of convulsive movements of pharynx, larynx or of the general musculature. The animal is entirely tractable and seems to desire to be helped in drinking and eating.

We have not been able to find a case of dumb or paralytic rabies, indeed any well established case, with which to compare these symptoms. The above outline seems to be clearly enough defined and should not be mistaken for hydrophobia. The desire for water, the slow pulse, the vomiting and purging all point against this latter.

When small repeated doses are given (.01 gram was used in this work) the effect is transient. There may be a little vomiting with very pronounced distaste for food on that day, and on the morning after the dose, two or three rather loose stools may be found in the cage. The dog then proceeds to take food and water with relish. One dog was given 8 doses in three weeks, losing only 4 ounces in weight. This quantity would seem to approximate what a dog might pick up around a stable on stray objects which had been soiled with the drug or carried by vermin.

The following is an autopsy report on one of our dogs. The picture is very clear as against that of Rabies. There are no negri bodies or anything which might be mistaken for them. The pronounced congestion is common to irritative poisons. This work is being continued and we hope to be able to publish a tabulated list of symptoms of the two conditions which may help in diagnosis and prevent the killing of dogs which are not mad.

Dog No. 5, Autopsy performed 9 hours after death.

Well preserved, well nourished dog, evidences of vomiting, frothy mouth, mucous membrane of the mouth slightly congested.

Lungs congested and edematous with a narrow rim of emphysema just beneath the pleura. No consolidation.

Lymph glands, small, soft, homogeneous, congested and anthracotic.

Heart distended, stopped in diastole. Chambers distended, with dark semi-clotted blood; in the conus arteriosus chicken fat clot. Muscle pale, homogeneous except near auriculoventricular septum, where it and the areolar tissue are congested. Valves are negative and seem competent.

Liver, normal in size, form and consistency. Edges sharp, section uniformly congested, slightly opaque and shows dense capillary congestion.

Spleen, normal in size and color. Slightly softer than normal. Uniform on capsule. Section shows slightly hyperplastic follicles with congested pulp especially around the follicles. Trabeculae not visible.

Kidneys, normal in size, shape and color. Capsule smooth, strips with a little difficulty but does not tear the surface. The normal purple zone between the cortex and medulla has a pale area in the middle, thus giving the impression of two purple lines, one at the junction and one in the medulla. The striae are normal, glomeruli not visible; on the surface beneath the capsule are several small, pearly, white, sharply marginated, slightly depressed areas about 1 m. m. across which have somewhat the appearance of a hyaline tubercle.

Stomach, congested on serosa, slightly foul gray granular fluid, mucosa is dull, pale purple color; the rugae are not enlarged, but slightly more tortuous than normal.

Pylorus is normal; the gall duct is patulous, the gall bladder is filled with dark viscid brown fluid. Mucosa of the duodenum is swollen, especially at the tops of the folds, and the evidences of violent contraction may be seen in the alternate pale and congested areas from the mucosa all the way through to the serosa. The jejenum is violently congested, mucosa soft and almost entirely disintegrated in places while in others it maintains its position. In the ileum the mucosa becomes paler and there are many sub-mucous hemorrhages varying from 1 to 5 m. m. in diameter; still further on the mucosa becomes almost normal in color and consistency, and the gut contains only a little tenacious yellow mucus. No food is present in any place. Ileocecal valve is normal in color and the cecum contains a little inspissated feces, the longitidunal folds are swollen and more tortuous than normal, and their tops are markedly congested, almost hemorrhagic.

Brain; dura fairly adherent along the longitidunal fissure, otherwise negative. Brain itself slightly congested on the surface. Section negative. Section of cerebellum into the brain of rabbit No. 35. Section of cerebral cortex into rabbit No. 33. Section of ammons horn into rabbit No. 34. None of these rabbits developed anything abnormal.

MICROSCOPICAL NOTES.

(1) Cerebellum: as in the first animal similarly poisoned and examined histologically there are to be noted more or less evidences of oedema and cytolytic changes involving the cells of Purkinje. No appearances at all suggesting Negri bodies.

(2) In the section of cornu ammoni there are minor evidences of oedema from the rather large spaces about the large multipolar cells and blood vessels; but the ganglionic cells are practically normal. In the cerebral cortex less marked oedema and a moderate injection of the pial vessels exist; and the ganglionic cells here show slight retrograde changes, much less marked however, than in case of the cerebellum.

(3) Cardiac muscle; presumably from the shape of the section taken from the right ventricular wall, shows some slight loss in the definiteness of the transverse striations and at places a little undue granularity of the muscle substance (probably a slight cloudy swelling). It is not marked, and there are no other features of importance noted.

(4) Wall of stomach, section taken from the cardiac end shows nothing of importance. There is a slight loss of the surface epithelium, which may well be from artefact. The glands are large, the acid cells particularly prominent and well defined; the peptic cells less well preserved and smaller. No especial injection of the mucosa, athough here and there are individual vessels injected with blood. No oedema of this membrane. The wall has in the sections separated below the muscularis mucosa; in this coat a number of the veins are turgid with blood. The muscles and outer coat seem practically normal.

(5) Several sections from the small intestine all show more or less catarrhal inflammatory change, injection of vessels, some destruction of surface epithelium and of the villi themselves; a variable but notable number of goblet cells in the crypts, some oedema of the villi and interglandular tissue of the mucosa. Similar congestive and oedematous changes in the submucosa and muscular coats.

(6) Liver; shows as its most marked feature a fairly distributed hyperemia, portal, central and capillary. There is no appreciable abnormality in the capsule or in the perilobular structures. The cells stain well, but are perhaps a little too granular and perhaps slightly swollen,—in neither case very distinct.

(7) Pancreas. This section is poorly shown, probably mainly from some fault in preparation (looks as if over-heated). There was evidently a rather marked hyperemia and the tissue seems quite loose (either oedema or artefact). The cells stain densely and without definition, seem to have largely fused together within the acini.

(8) Kidney, shows widespread injection, involving the arterial as well as the venous side of the circulation of the organ. There is well marked cloudy swelling and at places necrosis and desquamation of the tubular cells of the cortex, and mainly in the tubules but also in slight measure in the Bowman's capsules, there is more or less graular coagulate of an albuminous exudate. The interstitial tissues are mainly uninvolved, but at places show a little oedematous looseness.

(9) Spleen, capsule normal. Malpighian bodies large and about the peripheries loose and showing a slight perifollicular space because of oedema. Pulp generally markedly congested, not hemorrhagic and not pigmented. No special hyperplastic changes in pulp, follicles, or trabeculae. Capsule normal. Microscopical diagnosis; Oedema of brain, catarrhal enteritis; acute parenchymatous nephritis.

V. Autopsy Notes on Mock Sem, Leprosy and Tuberculosis.

Specimens from the post mortem examination of the Chinese patient of the Department of Health were sent to the Laboratory and examined by Dr. Allen J. Smith who reports the following:

The lungs were found extensively involved, showing both marked diffuse caseation and chronic ulcerative lesions, with enlarged and caseated bronchial lymph nodes. There was extensive ulcerative tuberculosis of the intestines, the ulcers large, numerous, with thick, overhanging edges, smooth, indurated bases and numerous miliary tubercles showing peritoneally in the wall of the intestine at the base of each ulcer.

For histological purpose there were sent to the Laboratory portions of the lungs, heart wall, liver, spleen and kidney, several cutaneous nodules from the ear lobes and a small bit of thickened and indurated skin from the face.

(1) A section of a nodule from the ear lobe shows the characteristic features of an active leprous hyperplasia, and with special staining exhibits a vast number of typical leprosy bacilli, in and between the deeper epithelial cells of the epiderm, in large lepra cells and smaller endothelioid cells and in the tissue spaces between the tissue elements of the thickened corium. Some proliferation of the epiderm, with a slight but clearly excessive penetration of the interpapillary portions into the corium, has taken place, and at least one epithelial concentric nest was noted quite a distance below the surface. The main elements forming the nodule are in the corium, where the old fibrous matrix is thickly infiltrated by embryonic cells of fibroblastic and endothelioid type, these constituting the bulk of the tissue in most microscopic fields. Scattered mast cells, lymphocytes and small plasma cells, and occasional large endothelioid cells (lepra cells) and occasional polynuclear leucocytes (some eosinophilic) are encountered.

In the skin of the face the process is evidently older; the corium is thickened largely by a fibrosis, with much smaller number of the infiltrating cells mentioned in connection with the preceding section. The epiderm shows a more definite penetrating growth, at places exhibiting slender root-like extensions into the corium which often unite into a rather fine reticulum just under the major part of the cuticle, reminding one of Unna's reticulate type of epithelioma, and occasionally showing well developed epithelial pearls. With these differences, however, the general characteristics are the same.

(2) Sections of bits of pulmonary tissue all show tuberculous changes, ranging from typical milary tubercles to rather large conglomerates with extensive caseation. For the rest catarrhal changes, hyperaemia and oedema with occasional foci of suppuration in and about bronchioles make up the general picture.

(3) Wall of heart. Epicardium missing from sections examined. No alteration of endocardium. Myocardium somewhat congested and fibres rather loosely separated from each other, probably by an oedema. The fibres themselves are typically rather slender, but show no loss of striation and no pigmentation. The nuclei are as a rule well stained and clear; are for the most part of relatively small size. No fibrosis of the tissue, and no alteration of the wall of coronary branches caught in the section.

(4) Liver. Capsule normal. No overgrowth of Glisson's capsule and no important vascular changes. Liver cells generally rather granular and somewhat swollen, a few showing fatty infiltration appearances. The main feature of the sections examined is in the presence of a number of miliary tubercles, mainly of gray type met here and there both in the perilobular tissue and in the interior of lobules.

(5) Kidneys, are not, from the sections examined, seriously changed. There is a scattered cloudy swelling of the cells of the cortical tubules; and in contrast there are many tubules which show no such alteration. At places the tubules are widely distended by a granular coagulated material within them, and occasionally such material exists in Bowman's spaces. No special interstitial change but a few of the tufts are more or less fibrosed. There is a moderate capillary injection; blood vessel walls normal.

(6) Spleen. The main feature here is a rather marked diffuse, endothelial hyperplasia of the pulp. A few miliary tubercles have been noted in the tissue in addition. The tissue is moderately hyperemic, not pigmented; the malpighian bodies are of normal size and structure; no important change in the wall of blood vessels; no marked overgrowth of the trabeculae of the organ.

PRODUCTS OF THE TUBERCLE BACILLI.

The Laboratories of the Department of Health have been busy since their opening following a line of work begun nearly a score of years ago by the Commissioner of Health, with dead, avirulent or altered tubercle bacilli and an extraction by salt solution of virulent organisms after the wax of the bacteria had been softened by ether. The work at that time was not done in a manner permitting standardization of the products in terms of the organisms. Indeed no one has elaborated an exact method by which products of the tubercle bacillus may be standardized in any terms. Our work has not allowed any more definite statements in regard to toxicity of our products

than could be said of Dr. Dixon's original solutions or of the more widely used old Tuberculin of Koch. This presentation will introduce our present methods of production of the vaccines or toxins which are based upon weights and percentages. A description of the cultures which are used for making our toxins is as follows:

1 a. An old bovine stock used in this Laboratory for 2 years with 2 passages. The original stock is practically as virulent as the newer growths. One milligram will kill a guinea pig of 400 to 500 grams in six to eight weeks.

2 c. A human stock used the same length of time with one transfer through animals, one milligram will kill a 400 to 500 gram guinea pig in six to ten weeks.

Our solid cultures are kept on blood serum plus neutral dextrose broth. The organisms are grown on neutral 5 per cent. glycerine veal boullion. The growths from which these products are made are of ten weeks duration on the fluid medium. Cultures are grown at 37 degrees C. When the growths are mature they are killed by raising to the boiling point in the autoclave and then allowed to remain in the Arnold Sterilizer with the door open two hours after the water has reached the boiling point. The organisms are then filtered off and kept under sterile precautions while the fluid filtrate in used for old tuberculin. The handling of the cultures for the product made of living organisms will be described later. The products to be described consist of dead and partially degreased organisms called No. 5, and a salt solution extract of living tubercle bacilli called No. 10. The facts to be considered about these products are included in the following headings:

NO. 5, DEAD AND PARTIALLY DEGREASED TUBERCLE BACILLI.

NO. 10. SALT SOLUTION EXTRACT OF LIVING VIRULENT TUBRCLE BACILLI.

1. Method of Production.
2. Method of Standardization.
3. Method of Arriving at Dosage.
4. Toxicity.
5. Effect upon Temperature of Healthy Animals.
6. Effect of Temperature of Tuberculous Animals.
7. Effect of Repeated Injections into Healthy Animals.
8. Effect of Repeated Injections into Tuberculous Animals.
9. Effect of Second Dose after Incubation Period.
10. Effect of Injection of Tubercle Bacilli after Incubation Period.
11. Effect of Large Dose Subsequent to Injection of Tubercle Bacilli.

Action of the two products toward one another.

12. Effect of Sensitization for one another.
13. Effect of Alternate Injection.
14. Effect of Double Injection into Tuberculous Pigs.

NO. 5. DEAD AND PARTIALLY DEGREASED TUBERCLE BACILLI.

1 and 2. Method of Production and Standardization. After the bacillary mass is removed from the filtrate it is dried of excess of moisture, over night perhaps, in the incubator, and then it is dried in a vacuum dessicator over sulphuric acid until it becomes brown and brittle. The masses are then broken into small fragments and placed in a soxhlet. An equal quantity by weight of human and bovine bacillary mass is used. The first extraction is done with absolute alcohol and is continued until the brown color of the distillate has disappeared. The alcohol is then replaced by ether and the extraction is continued until the cooled ethereal distillate is practically clear. Absolute clearness is impracticable to obtain because it seems impossible to exact all fat and wax from the tubercle bacillus. Vaudremer and Martin say that six weeks extraction with petroleum ether will not remove all the fat. The extraction necessary to bring about the above result will last six to eight days of nine hours each, depending upon the size of the clumps. When the ether extraction is complete, the mass dried twenty-four hours at 45 degrees C. The resulting mass consists of dirty yellow gray granules which break up easily into a slightly greasy powder. This is not soluble in water, salt solution, alcohol or ether and when used must be ground up in definite quantity and the per volume weight determined. The usual method is to grind up a large quantity, without previous weighing, in a ball mill with a small quantity of salt solution. A definite quantity of this suspension, say 20 cubic centimeters, is evaporated to dryness in a tared watch crystal and the same quantity of the salt solution used to make the suspension is also evaporated. The difference in these weights will equal the weight of the degreased organisms in amount of suspension used. In order that the emulsion shall be homogeneous, the suspension after grinding is centrifuged, the supernatant liquid removed and resedimented in the machine. After a third centrifugalization one obtains a homogeneous emulsion which will stand without sedimenting for a long while. Any slight sediment which occurs after three to four weeks will shake up into perfect homogeneity. 8.64 milligrams to the cubic centimeter is the highest strength I have been able to obtain in perfect emulsion. The salt solution used is .6 per cent.

Microscopic examination of the mass after extraction shows chiefly unbroken organisms which take the acid-fast staining methods very faintly but clearly. The irregularity of staining characteristic of the tubercle bacillus is more pronounced. Careful observation with high objectives and oblique light shows no irregularity in the contour of the single cell but the edges of the stained portions seems more irregular than the untreated bacillus.

Microscopic examination of the ground emulsion shows many fragments chiefly single organisms and only occasionally two, never more,

clinging together. The staining is apparently the same as before grinding.

3 and 4. Method of Dosage and Toxicity. The difficulty of expressing the value of these products in any unit of toxicity or other property, has compelled us to adopt a dose which when repeated every week or ten days causes no loss of weight in a healthy or tuberculous guinea pig of 400 to 600 grams, the latter with a control pig of the same stock and injected with Tubercle Bacilli in the same manner, but not with this product. It is not necessary to give all the details of our primary experiments, but it will be enough to state that weekly injections of .000001 gram of the organisms will be withstood without loss of weight. Repeated doses of .001 gram will give emaciation in healthy animals and rapid loss with death in infected pigs. No limit can be set upon the dose however, as one pig will endure larger doses or more frequent repetition than another. Several tests upon tuberculous pigs to obtain a definite relation between the degree of infection and the dose of this product have had no satisfactory result. Large doses such as .025 to .05 gram will cause loss of weight in healthy pigs and in tuberculosis pigs rapid emanciation and death, but not in a few hours or with a hemorrhage into the peritoneum, such as Vaughan and Wheeler found with their cellular substance. Rabbits withstand larger doses in proportion to their weight than do guinea pigs, but they are nevertheless subject to the same general rules.

5 and 6. Effect upon the Temperature of Healthy and Tuberculous Animals. The effect of .000001 gram upon the temperature of healthy rabbits and guinea pigs is nil. This dose will produce no reaction in tuberculous rabbit but a slight rise is appreciable in an infected guinea pig's temperature after this dose. Doses of .0001 or .001 gram will produce a rise in both animals varying from .6 degrees to 1. degree F. Doses of .005 and .01 gram will give a rise of 1 degree to 2 degrees F. These large doses will have no effect in raising the temperature of either animals if healthy, but .005 to .01 gram will sometimes depress the temperature of a healthy guinea pig .6 degrees to 1. degree F. if given into the abdomen, but not when given under the skin. Injections of .01 to .02 gram have no effect upon the temperature of healthy cows; such doses given to tuberculous cows are followed by a slight irregularity with a tendency to rise but with no sharp reaction.

7. Effect of Repeated Injections of Healthy Animals. If the standard dose of .000001 gram be given either under the skin or into the peritoneum of healthy pigs or rabbits, at intervals of one week, no loss of weight or other sign appears. If loss of weight occur, it will be regained if the injections be discontinued for one or two weeks.

Attempts at active immunization have been made but as yet we can say little positive in this respect. One set of three pigs lived on the average of two weeks longer than the control. This was however, while we were still using the large doses (.0001 gram) and a table would show nothing more than this statement. Of our later experiments we have three pigs which received twenty-three injections before the organisms. They still live. They have gained from 350 to 600 grams in nine months and have lost no weight since injections of the organisms.

8. Effect of Repeated Doses into Tuberculous Animals. The vaccinations of infected animals with this material has had about the same history as the attempts at active immunity but with a little better success. Our first attempts were with virulent organisms but it was found necessary to use less virulent ones. Since introduction of our small stable dose, the results have been much better. Herewith is a chart of one set of animals. It will be seen that the animals had some resistance from the degree of infection and length of life. Two unfortunately died of pneumonia.

No.	T. Bc.	Inj. of No. 5.	Weight change.	Length of life.	Post Mortem.
277	2.mg.	3	105 grm.	33 days.	Caseous of liver, spleen, omentum and gland.
78	2.mg.	1	60 grm.	10 days.	Nodule at site of inoculation catarrhal pneumonia.
279	2.mg.	1	0	21 days.	Nodules at site of inoculation, cheesy T.Bc. in liver, omentum infiltrated.
280	2.mg.	Control.	----------	9 days	Miliary and diffuse exudative.

We have three animals which have received sixteen doses each. They and the control still live, so that little can be said aside from the fact that the weight change is greater in the control than in the infected animals.

9, 10 and 11. Effect of Sensitizing doses of No. 5 for itself, and for Tubercle Bacilli and the effect of the latter as a Sensitizing body. Injection of .005 to .01 gram of No. 5 will sensitize a guinea pig so that a subsequent dose of the same or larger doses will cause a condition of restlessness and irritability for a short time followed rapidly by depression lasting a few hours. This same dose will not sensitize for subsequent injections of tubercle bacilli. These reactions will occur if the injections be made under the skin or into the abdomen. Two doses of .01 gram will not cause a condition of hypersusceptibility to the tubercle bacillus and from one experiment no

resistance seems to occur in refractory pig, either those made so by two close inoculations or in those which have passed through the second injection. An injection of .01 gram of No. 5 and .5 milligram tubercle bacilli will not sensitize for a subsequent injection of No. 5 in doses of .005 or .025 gram. In the presence of tubercle bacilli, injections of this material would seem harmless.

NO. 10. SALT SOLUTION EXTRACT OF LIVING TUBERCLE BACILLI OR TUBERCLE BACILLI EXTRACT.

1 and 2. Method of Production and Standardization. This product is made from living organisms removed from fluid media. An equal weight is taken from human and bovine strains, dried of excess water in the incubator and then washed in an excess of ether. This is renewed when it has removed the last remnants of water.

This fat separates so that it collects at the bottom of the vessel and may be removed by a Pasteur Pipette. After removing the second ether, the mass is allowed to dry until no more ether odor is perceptible. Then the separated fat is removed. The mass is weighed, ground thoroughly in a mortar and suspended in ten parts of .6 per cent. salt solution. This suspension is carried in a shaking machine eight hours and allowed to stand sixteen hours at room temperature. It is then filtered several times through porcelain, the filtrate being a light amber or pronounced straw colored fluid, our product No. 10. The standardization of the extract must depend upon its equivolent in tubercle bacilli. One cubic centimeter represents the extract of .1 gram of the organisms. Repeated microscopical examination of the sediment of large quantities fails to reveal any bacteria and injections of a single large or repeated small doses do not produce tuberculosis.

The following is a chemical analysis of the product No. 10.

	Human.	Bovine.
Color,	Deep straw yellow,	Straw yellow.
Reaction,	Faintly acid,	Faintly acid.
Total residue,	1.27%	1.23%
Sodium chloride,	0.74%	0.68%
Organic matter,	0.46%	0.44%
Sulphates,	Slight,	Slight.
Calcium,	Slight,	Slight.
Odor of residue on evaporation,	Slightly ammoniacal,	Slightly ammoniacal.
Color tests of residue with strong acids and alkalies,	None,	None.
Tanret's tests for albumens,	Positive,	Very faint.
Trichloracetic acid test for albumens,	Positive,	Faint.
Salicylsulphonic acid test for albumens,	Negative,	Negative.
Nitric acid and heat test for albumens,	Negative,	Negative.
Mayer's reagent for alkaloids,	Negative,	Negative.
Alphanaphthol test for carbohydrates,	Faint,	Negative.
Nessler's test for ammonium compounds,	Strong,	Positive.
Ammonium molybate test,	Positive,	Positive.
Tannic acid test,	Very faint turbidity,	Very faint turbidity.

We are now at work to determine the identity of the small quantity of proteid indicated in the analysis.

3 and 4. Dosage and Toxicity. As is the case with No. 5 and other tuberculins, we were compelled to establish the dosage of No. 10 by experiment. This product is distinctly more toxic than No. 5, but not so much so as old tuberculin. The glycerine content of the latter is undoubtedly the largest factor in its toxicity. In No. 10 this is entirely absent. Repeated injections of .001, .002 grams or more will cause a rapid loss of weight in both healthy and infected guinea pigs, in the latter case more rapidly than infected animals of the same stock not receiving the toxin. Guinea pigs will recover their weight if allowed to rest after one or two injections, but usually fail to do so if they have received several doses of this size. Guinea pigs of 400 to 500 grams will withstand weekly injections of .0001 gram if their weight be watched and rest given should any loss occur; some have actually gained a great deal under careful treatment. Doses up to .2 gram will not kill in a few hours or days as is the case with some solutions of bacterial proteids. The dose of .0001 gram has been taken as our standard therapeutic dose. Efforts to establish a quantity of this product which will prove fatal in tuberculous guinea pigs of standard weight have resulted in failures. Normal rabbits will withstand large quantities of this solution but tuberculous rabbits seem quite as susceptible as guinea pigs, if not more so. One rabbit died in six days after a dose of .01 gram while controls of the same lot lived six weeks longer.

5 and 6. Effect upon the Temperature of Healthy and Tuberculous Animals. The effect of all doses of this tubercle bacilli extract upon the temperature of healthy guinea pigs, rabbits and cows when given under the skin is nil. There may be a slight fall of temperature in the first named animal when the dose is given into the peritoneum. The following is the effect upon rabbits and guinea pigs, three to four weeks tuberculous by the injection of 1. milligram bovine tubercle bacilli.

	Rabbits.	Guinea Pigs.
.0001 grm.	0	.4 deg. F.
.01	1.6 deg. F.	1. deg. F.
.1	1.8 deg. F.	2. deg. F.
1.	Not tried.	

Injection of .4 gram into a tuberculous cow subcutaneously results in a slight but definite rise averaging .6 F. This is not sufficient and a more pronounced rise will be obtained when the appropriate dose is determined.

7. Repeated Injections into Healthy Animals. When starting this work the dose of the filtrate equal to the extraction of .001 gram was used. This has however, proven too great. In one set of animals in which this dose was used, both the prepared pigs and the controls died within one week of one another, and with the same kind of lesions. Since the dose has been decreased, several pigs remain having received eighteen to twenty injections with either a stable weight or a slight increase and no loss since receiving the tubercle bacilli. Nothing can be said at present in regard to the active immunity stimulated by this product. By careful watching the pigs withstand weekly inoculations of .0001 gram quite well.

8. Effect of Repeated Injections into Tuberculous Animals. Repeated injections of this solution into infected guinea pigs does not seem to postpone the fatal issue to any material extent, but they seem to have some effect upon the character of the lesions. The animals which live the longest show a tendency to regression of the lesions. In one or two animals of a later experiment this has been repeated. Especial attention is called to animal No. 293 in the accompanying chart. It lost 130 grams in twenty-seven days yet showed more resistance than the others.

	T. Bc. inj.	Inj. No. 10.	Weight change.	Life.	Lesions.
No. 293	1.mg.	2	—130 grams.	27 days.	Caseous in spleen, omentum but firm, few small tubercles in lungs, diaphragm and glands.
No. 292	1.mg.	2	—75 grams.	31 days.	Similar to No. 289 but not so much degenerated. Firm congestion and exudation around process.
No. 289	1.mg.	0	—30 grams.	20 days.	Pleurisy. Caseous tuberculosis of liver, spleen and lymphatics active progressive.
No. 290	1.mg.	2	—30 grams.	23 days.	Same as 289.
No. 291	1.mg.	2	—45 grams.	21 days.	Same as 289.

9, 10 and 11. Effect of Sensitizing Doses of No. 10 for itself and for Tubercle Bacilli, and the Effect of the latter as a SensitizingBody. One injection of No. 10 will produce a condition of hypersusceptibility for a second injection, after the lapse of fifteen days incubation period. The symptoms following the intoxicating dose consist of depression and nervousness with great irritability and excitement upon the slightest disturbance. A sensitizing dose of .01 gram of No. 10 will prepare for an intoxicating dose consisting of tubercule bacilli.

The symptoms are irritability, nervousness, scratching at the head, irregular respiration and trembling. This occurred in the first few minutes after injection and was followed in twenty minutes by quietness and depression which lasted a few hours. On the other hand a primary injection of tubercle bacilli also prepared for an intoxicating dose of No. 10. The symptoms are the same as those just mentioned but not quite so marked. The practical indication here seems to be to perform the first two injections in any animal within the incubation period and throw it into the refractory stage at once. Two injections of .02 gram of No. 10 will cause no susceptibility to a third injection consisting of organisms and from one experiment, no refractory state to this third injection is established. Action of these two products toward one another.

12. Effect of sensitization for one another. As has been stated above each of these products will sensitize for itself but our experiments show that one injection of No. 5 will not prepare for a subsequent dose of No. 10. The reverse is also true. The practical indication is that no harm can come from these materials in therapeutics if used together alternately.

13 and 14. Alternate and Combined use. The suggestion made at the end of the last paragraph that the alternate use of No. 5 and 10 would be harmless refers to symptoms of anaphylaxis in healthy animals. Experimentation must show whether or not this method is available for treatment in active tuberculous cases; healthy pigs withstand alternate doses fairly well but a close observation must be made of their weight because it sometimes falls. This in an indication to stop injections until the animals regain their loss. Our first experiments upon the effect of alternate and combined doses in tuberculous animals were cut short by an accident in our animal room. They seemed to indicate from the first few tests that a marked loss of weight and irregularity of temperature will occur and that a very small dose must be used.

PATHOLOGICAL NOTES.

Our observations upon the pathology in guinea pigs after being injected with these products are intesting. Our attention has been directed principally to the spleen and the regional lymph nodes. The former is the more important. After treatment with No. 5 there are often many small pale areas on and near the surface of the spleen quite suggestive of tubercles. There are centres of endothelial hyperplasia both in the follicles and in the pulp, chiefly the former. These areas are surrounded by a zone of small lymphoid cells. The picture is not that of a specific tubercle. There are no polynuclears in the vast majority of them. Practically none of them have softened or degenerated as seen in the areas of endothelial hyperplasia in this

organ after treatment with old tuberculin or serum extract. In no case were acid fast organisms demonstrable in them. The regional lymph nodes also show endothelial hyperplasia but by no means as marked as in the spleen. A non-specific focal necrosis is very occasionally encountered but it is not nearly so plain as those seen after serum extract or tuberculin treatment.

In spleens of guinea pigs dying from or being killed after injections of No. 10, the only histological change is a follicular lymphatic hyperplasia. The presence of necrosis has not been noted. This follicular proliferation is also met in the regional lymph glands.

SPECIAL REPORTS.

10—17—1908

SOME IMPROVEMENTS

IN THE

STERILIZATION OF CULTURE MEDIA, WITH ESPECIAL REFERENCE TO THE FRACTIONAL METHOD.

BY D. RIVAS, BACTERIOLOGIST.

Pennsylvania State Department of Health Laboratory.

The not infrequent occurrence in the course of bacteriological research of discrepancies of results, or even of total failure of the experiment when apparently the technical procedures were faultless, coupled with apparently inexplicable contaminations in culture or in a medium after storage for a time, have led the writer to suspect the methods of primary sterilization in vogue as lacking uniform sufficiency and induced the following study of this subject:

In a medium which had been sterilized in the autoclave at 15 to 20-pounds pressure for from fifteen minutes to one-half hour, and thereafter kept at room temperature and examined daily, it was sometimes observed that in the course of a few days a growth had occurred in some of the tubes, and only in exceptional instances were the tubes all free from contamination after a period of from three to six months. In case of nutrient gelatin, sterilized at 10-pounds pressure for ten to fifteen minutes, no instance was observed during the period of this study in which all of the tubes remained permanently sterile; and in one lot, after maintenance of the tubes for one to two weeks at 37 degrees C., over one-half were found contaminated. Similar results were obtained with culture media sterilized by the fractional method, as usually recommended (heating on three successive days at 100 degrees C. for thirty minutes, with the

media left at room temperature in the intervals). With such faults in mind it was deemed desirable to make a close study of the causes of these irregularities and to attempt some modification of procedure promising greater certainty of complete sterilization.

Satisfied from comparative examinations that the fault is one entering from incompleteness of primary sterilization, it at once suggested itself that an important proportion may be due to the presence of spores resistant to the ordinary measures to which the medium is subjected. Apparet, a century ago, was the first to discover the method of conservation of preserves in stoppered bottles after the bottles had been boiled; but in his experience, in spite of boiling the containers well for several hours, it was not an infrequent occurrence that the preserves spoiled. Globbin, in 1888, observed in case of an organism isolated from potato that the spores were capable of resisting 100 degrees C. for from five to six and one-half hours, of withstanding 109 degrees to 113 degrees C. for three hours, and required for destruction exposure to temperatures of 113 degrees C. to 116 degrees C. for twenty-five minutes, or of 130 degrees for three minutes. In the same year Koch found the spores of B. carotarum to resist 100 degrees C. for eight hours, and to require four hours' exposure to 130 degrees C. sterilization. In 1894 Flugel obtained similar results with spores of certain bacteria isolated from milk. Christ, in 1895, found spores of organisms isolated from the soil capable of resisting 130 degrees C. for one minute. The valuable researches of Heinze, in 1903, are well known in connection with B. megatherium, B. ellembachensis, and B. subtilis, the spores of the last capable of resisting 100 degrees C. for three hours. I was able to observe in experiments made along the same line in the Institute Pasteur the capability of the spores of B. subtilis to resist exposure for two and one-half hours to 100 degrees C. In case of the bacteria isolated from fresh bread it is familiar knowledge that their spores have resisted the heat of the baking oven. Many similar common examples of such resistive power readily occur to mind; and literature records numerous observations of facts of the same import, indicating the possibility of the dependence of failure to destroy original contamination of material by such heat-resisting entities.

It must be quite probable, too, that in addition to the above possible fault the protection afforded to contaminating organisms against the sterilization exposure may contribute in no unimportant measure to the same end. While the B. tuberculosis and the other non-spore-bearing organisms are easily destroyed by a direct exposure to 60 degrees C. for from ten to fifteen minutes they are capable when protected by albumenoid substances (sputum, feces, etc.) of resisting for long time an exposure of 100 degrees C. While in Berlin the writer had the opportunity of observing in the case of the tubercle

bacillus, the retention of virulence by organisms obtained in scrapings from the walls of one of the tuberculosis wards after the room had been empty for over four months. Explicable in the same principle, it is a well-known fact that the sterilization of bouillon or any liquid medium is more easily accomplished than of agar or more especially nutrient gelatin; in fact, the writer has observed the complete sterilization of bouillon after a single exposure of thirty minutes to 100 degrees C., but has never obtained similar results with gelatin.

Although the above factors (special resistance of contaminating spores and the protection afforded contaminations by the medium) might well explain imperfections of sterilization by the autoclave, it suggested itself that in case of fractional sterilization (in which as is known the spores are permitted to germinate in the intervals of heating and in their vegetative form become susceptible of destruction by the subsequent heat exposures) this failure might find another explanation, and with this in view the following investigation was pursued.

Nutrient gelatin was distributed in tubes previously sterilized by dry heat at 180 degrees to 200 degrees C. for fifteen minutes or longer (until a browning of the cotton plug appeared, which indicated the decomposition of the organic matter or complete sterilization) and sterilized by fractional or intermittent exposure to 100 degrees C. for fifteen to thirty minutes on three successive days, being left at room temperature during the intervals; but in spite of all precaution taken, in a number of these tubes, after storage at room temperature or in the incubator at 37 degrees C. in the course of from twenty-four hours to several days' contamination became apparent, the varying time apparently being related to the temperature of storage locality. This last at once suggested that in case of contamination by spores resistant to heat the room temperature exposure of the intervals might very well not be the most favorable temperature for germination of such spores in the vegetative forms; in other words, the spores present originally and not destroyed by the exposure to 100 degrees C. in the first might at the temperature of the interval remain as such (unchanged) and be equally resistant to the heat of the sterilizing process on the second day, and that the same results might follow for the second interval and on the third heating, and that subsequently during the prolonged storage of the medium they might germinate. An experiment made in this line proved such to be the case.

Old cultures of Bacillus subtilis and spore-bearing moulds were inoculated in different media and left at room temperature, daily observation showing the medium to remain perfectly clear for from one to seven days, according to the temperature of the room and season of the year. These two organisms were preferred because,

in the writer's experience, these have been found the most common and in many cases the sole agents of medium contamination. This variation in rapidity of development suggested that in the process the room temperature intervals might prevent the germination of spores, as this might well be deficient, and that, therefore, it must be desirable to provide in these intervals of sterilization surroundings of a temperature more favorable for the spores to germinate and cause the vegetative stage of growth. With this in view gelatin medium, after the first exposure to 100 degrees C. for thirty minutes, was tubed—the tubes divided into groups. Part were placed in the incubator at 37 degrees C. for six hours, other series were incubated at the same temperature for twelve, eighteen, and twenty-four hours, respectively; after such periods resterilization at 100 degrees C. for thirty minutes was again performed for each group and the tubes stood at 37 degrees C. for observation. As was expected, but few tubes subsequently were found contaminated, the results being much more favorable than when the room temperature had been employed in the intervals of heating. Further, it was noted that the short interval of incubation, for but six hours, was too short for germination of the spores even at body temperature; and that on the other hand, eighteen to twenty hours' incubation was too protracted, since in these periods the medium became undesirably clouded for growth of the organisms, while intervals of incubation for from twelve to eighteen hours gave the most favorable results. Following these determinations another series of observations were made for the purpose of comparisons between the common practice of heating three times in fractional sterilization and two exposures. A series of tubes were heated for thirty minutes to 100 degrees C., then incubated at 37 degrees C. for from twelve to eighteen hours and submitted to a final sterilization at 100 degrees C. for thirty minues. A second series of tubes were exposed on three successive days for thirty minutes at 100 degrees C. and incubated at 37 degrees C. for twelve hours in the first interval, and for twenty hours in the second interval. The results in these two series were practically identical, both being satisfactory.

With a view of determining the possibility of completing a fractional sterilization in a single day, as in case of need of some media for which the use of the autoclave is unsuited, as a sugar or gelatin medium (the high temperature of the autoclave producing undesirable changes in such media), a medium was prepared early in the morning and sterilized at 100 degrees C. as usual at about eight o'clock, then incubated at 37 degrees C. until about five o'clock in the evening, when it was again sterilized as previously. The results were quite satisfactory, again proving the efficiency of the method and establishing the advantage of material saving of time. Such procedure can,

however, be recommended only for use in emergencies, as the writer feels the need of strongly emphasizing the desirability of incubating any medium for at least forty-eight hours after sterilization is supposed to be complete, in order to detect and then eliminate any possible contamination.

It is deemed unnecessary to recommend or outline any special rule for the above procedures. Good results may be obtained by the usual practice of sterilizing on three successive days, with a first interval of twelve hours for incubation and a second interval of twenty-four hours; or by sterilizing but twice, with an interval of twelve hours for incubation; and as just stated, the sterilization can be completed in a single day. The routine method followed by the writer, with most satisfactory results, includes the preparation of the medium early in the morning and at once exposing it to 100 degrees C. for about ten or fifteen minutes, then incubating at 37 degrees C. for six to eight hours during the same day, and toward evening again subjecting it to 100 degrees C. for fifteen to twenty minutes, followed by a second interval of incubation at 37 degrees C. over night, and a final heating the next morning to 100 degrees C. for thirty minutes. This shortens the general routine by one full day, and, too, the heat exposure is reduced by one-third, each a material advantage when at the same time the final result is not impaired, but, as above indicated, rendered more sure of success. The precise method may vary with the judgment of each worker, the writer's only desire being to point out the necessity for providing a temperatture during the intervals of heating which will favor the germination of the spores, so that in their vegetative form they may be the more certainly destroyed at the next period of heating, and at the same time to urge the fact that the ordinary room temperature cannot by any means be regarded as favorable for this purpose in the intervals commonly allowed between sterilizations.

There is a further feature bearing upon the above which it is not inappropriate to bring forward in this relation. In spite of all precautions ordinarily taken in sterilizing media either in the autoclave or by the above outlined fractional method the writer has not found it always possible to avoid contamination of some of his tubes. It must be recalled that by either method the cotton plugs become more or less wet from exposure to the steam atmosphere and from the vapor arising from the heated liquid medium; and it is to be expected that by mere capillarity a more or less continuous thin sheet of the condensed moisture will intervene between the plug and the glass of the container (present in the cotton plug as well, but, perhaps, not in as perfect continuity). Through such a continuous liquid it is possible that occasionally organisms coming from the air of the

open room in which the tube is cooling might be afforded a path of entry from the exterior to the interior of the tube; and it must be realized that the lower the room temperature when the tube is first brought from the heated sterilizer the more decided a current of air is drawn through the plug as the interior air becomes cool and contracts, possibly aiding in the introduction of organisms, as just suggested. To avoid such a possibility the transference of the medium from the sterilizer to an incubation oven at 37 degrees C. for at least forty-eight hours most clearly aid, drying the surface of the plug more quickly and at the same time permitting, to a less degree, the rarefied air in the tube to cool and condense rapidly. Personally, the writer is inclined to believe that lack of this precaution is not infrequently responsible for the contaminations which enter to spoil this or that experiment, to cause contradictory results in the work of the same or different investigators, and which have added much to the uncertainties and volumes of our bacteriological literature.

Some may be disposed to hold that if the medium has been properly sterilized, subsequent incubation for forty-eight hours, as above suggested, at 37 degrees C. is unnecessary. This is in theory true, but in practice what means do we possess of knowing surely whether the medium is pure, save by subjecting it to conditions known to be most favorable for growth of contamination, if perchance contamination exists? The time is past when water analysis was limited to its physical properties alone; and just as today no one would pretend to estimate the number of bacteria in a sparkling water or its sanitary condition by its clearness in the same way, we are not justified in assuming that because a sample of bouillon or other medium remains transparent after storage at room temperature or in the refrigerator, as usually recommended, under conditions unfavorable for the germination of spores possibly present, it is, therefore, a sterile medium. The procedure recommended is logically correct and so simple that no objections of inconvenience or lack of necessity should be held material against it; and it may be urged as a definite rule of procedure that in all sterilization by steam, whether in the intervals or after the fractional method, or after the use of the autoclave, the medium should not be directly exposed to room temperature or a lower temperature, but should be placed in the incubator at 37 degrees C. because this condition will both aid in early and certain detection of possible contamination, and will in some measure favor the exclusion of organisms, liable to be drawn into the container by air suction in undue moisture of the cotton plug. The writer might add, in conclusion, that it is his opinion that the fractional method of sterilization, as above recommended, might often with the advantage replace the autoclave not only in effi-

ciency of sterilization, but more especially as evading the production of undersirable changes which the high pressure and temperature of the autoclave have been found to produce in culture media.

SMALLPOX IN CUMBERLAND COUNTY.

REPORTED BY HARVEY B. BASHORE, M. D.
County Medical Inspector.

It is reported that some time in August, 1908, a farm hand from Reading came to Harry Hoopy's, back of Camp Hill; he became slightly ill and developed a rash. No doctor was employed. In due time Hoopy and his family became sick with the same disease; no doctor employed. Hoopy had a milk route in West Fairview-Enola district, and continued to serve his customers although there were many scabs on face and hands; so much for heresay.

In September there were cases of chicken-pox reported to the Department in the Bretz, Horning, Campbell, Gardner and Kunkel houses at Enola. Bretz and Horning being related to Hoopy, and Campbell, Gardner and Kunkel being neighbors and visitors at Bretz's. These cases reported by four different doctors,—were claimed to be chicken-pox, although in every family adults were affected.

On September 16th the Department began investigation and found every case to be typical smallpox. The Hoopy house was thoroughly fumigated and the other families quarantined for smallpox. Meanwhile the health officers were hunting "contacts." Ninety-three families comprising the Hoopy relatives and milk route were put under surveillance; one of these, Westfall, father-in-law to Bretz, having a case in his family, was quarantined. After this only four families became infected.

On September 18th Postmaster Hawbaker walked into my office with a third-day eruption of smallpox, having just returned from a convention in Ford City, Pa., and having left home four days before; he probably contracted the disease from one of the "perambulating" cases from Enola. The Post Office was immediately closed and thoroughly disinfected and then turned over to the Post Office authorities. I notified the Department of the trip of Wm. Hawbaker; his stopping places while at Ford City and the railway coach in which he traveled; from his case I believe only two or three new ones developed.

A few more "contacts" were hunted up and the epidemic at this place ended with Clara Boughter, who was quarantined on December 17th and with whom there had been no "contacts." In all twenty-nine cases. At the outset of the epidemic health officer Hoover resigned and I immediately sent for health officer Weaver, who served me most faithfully.

Although extreme vigilance was used in hunting "contacts" one escaped—Mrs. Curtis Walters of New Kingston, related to Campbell, in whose house she was probably the day it was quarantined. She went home and in due time so the story goes, she herself and children became ill with a rash (no doctor) and the disease was concealed for the time. Her husband became ill and on October 22nd, the second day of the rash, was found working in McCullough's store in Carlisle. He was immediately sent home and all "contacts" in Carlisle vaccinated and put on parole.

Meanwhile, we learned that the Walters woman, in the role of a book agent, had visited practically every house in New Kingston, and the whole community was put under surveillance, health officer Mackey being ordered to take up his residence in New Kingston.

In fourteen days the first crop of "contacts" developed in Harris, Hertman, Powley, Bishop and Cora Martin, a teacher in Fairview Hall School in Middlesex township; all were quarantined and about twenty-five "contacts" vaccinated and put on parole.

In fourteen days more the second crop developed in the houses of Powley and Hertman, already quarantined, and only one outside the Black family, which had been under quarantine; they having been vaccinated three days after contact. In this family one child developed a very modified case which consisted of only five pocks, but they were perfectly typical. Cases in this place all told twenty-one making a total of fifty for our epidemic and about four hundred "contacts."

On December 1st, William Walker of Carlisle, who had been in a factory visited by one of the Hertman children from New Kingston was found to have smallpox. On December 17th two other families

infected by Mrs. Knoche, who evidently had a mild attack, contracted from the same factory, developed. These cases of course belong to Carlisle. While this epidemic seemed to differ in no wise from any other smallpox epidemic the following facts attracted my attention.

1—All patients were unvaccinated save one and that forty years ago.
2—The unvaccinated in the quarantined houses invariably got smallpox except in one instance, while the vaccinated did not get it.
3—Vaccination one or two days after "contact" generally prevented the development of the disease; three or four days after it did not prevent.
4—One hundred and fifty (150) children were kept out of school for eighteen days, which is equivalent to twenty-seven hundred days of schooling lost to the children of Cumberland County on account of smallpox: vastly more than would have been lost by the enforcement of the vaccination law.
5—Five doctors called the disease chicken-pox, although in each house adults were affected.
6.—A number of children were reported to be vaccinated and had certificates of vaccination, who were not successfully vaccinated as shown by the entire absence of scar.

The epidemic was of the non-fatal type, although some of the cases were severe.

LEPROSY.

PROTOCTOL OF NECROPSY PERFORMED ON THE BODY OF MOCK SEM, DECEMBER 23, 1908.

By B. Franklin Royer, M. D., First Associate Chief Medical Inspector, and Paul A. Hartman, M. D., County Medical Inspector Dauphin County.

EXTERNAL EXAMINATION. The body of a very much emaciated male, about five feet long, weighing approximately eighty pounds and having the facies of the Chinese race. Rigor mortis is beginning in both extremities but is not yet marked. There are no marks of external violence. The skin over the lobes of both ears and over both malar bones and for a distance of 1.5 cm. below each malar bone is very slightly elevated, feels thick to the touch, leathery and indurated. Over the neck and trunk the skin shows no gross abnormality. Beneath the left scapula some suggillation is noted. On both lower legs, beginning below the head of the fibula and extending to the external malleolous, and across the crest of the shin anteriorally,

and to the medium line posteriorly, is an area of harsh, very dark brown skin, scaly and inelastic in character, badly nourished and presenting some resemblance to the skin of an alligator. The external genitals are apparently normal. A horseshoe slough said to be an ischio-rectal abscess is noted, on the left side of the anus, just outside the spincter.

INTERNAL EXAMINATION. Very little subcutaneous fat is found beneath the skin. The muscles are thin, flabby and paler than normal. The abdominal and thoracic viscera are still warm. 250 c. c. of straw-colored serum is found in the peritoneal cavity. The intestines bear a normal relation to each other and to the other abdominal viscera. On removing the breast-plate the lungs do not collapse. The thoracic viscera are apparently in normal position.

PLEURAE. The left pleural cavity is almost obliterated by old adhesions extending from the apex to the base and across the diaphragm. The right cavity is absolutely obliterated and it is with the greatest difficulty that adhesions can be broken up. At the apex of the right lung, in attempting to break up adhesions the visceral pleura was lacerated and the hand plunged directly into a large apical cavity.

HEART. The heart is large, being about 12 cm. long, 10 cm. broad and 6 cm. thick. The right wall is thin, the muscle is a light brown in color, is fairly firm and can with difficulty be lacerated with the thumb and forefinger. The right auricle is apparently empty. The right ventricle contains a small amount of chicken-fat clot. The left wall is thinner than normal. The color and texture correspond to the right. The left auricle is empty, the left ventricle contains an irregular mass of chicken-fat clot, extending a little way through the aortic orifice. Careful examination of the endocardium in all cavities fails to reveal any microscopic abnormality. The valves of both auriculo-ventricular openings and of the pulmonary and aortic outlets are practically normal. There is no palpable evidence of arterio-sclerosis. The coronary arteries are patulous.

LUNGS. The left lung was removed with considerable difficulty and on examination shows slight crepitation in the middle part of the left lobe and very slight crepitation in the upper part of the upper lobe. It is of a grayish purple color throughout the upper lobe and anterior and upper portions of the lower lobe, and at the base posteriorly is of a much darker and more solid purplish gray color. On section the lung cuts with gritty resistance and drips blood freely at the base, less freely in the upper portions. A considerable mass of purulent matter exuded as the section was made. The incision revealed four cavities in the lower part of the upper and in the upper part of the lower lobes, varying in size from 2 cm. to 5 cm. in diameter. No further section of this viscus was made.

The right lung, as already stated, was lacerated at its apex on removal. Slight crepitation was noted at the base of the upper lobe. There is no true middle lobe. A slight attempt at middle lobe formation can be noted in the lower part of what is really the upper lobe, at its anterior aspect near the median line of the body. In color the lung is grayish purple throughout with an added darker purplish color at the base. On section the lower portion drips blood freely while the upper portion drips less blood. The cavity which was opened on removal is of irregular shape and is approximately 8 cm. by 6 cm. by 4 cm. The section passed through three cavities, two of them in the lower lobe and one in the upper, varying in size from 1.5 cm. to 3.5 cm. Several smaller cavities were found in the posterior portion of the upper lobe, but not more than a centimeter in diameter.

The bronchi contain considerable mucus and purulent brownish-colored fluid. The mucous membrane of the bronchi is slightly injected in irregular areas. The peri-bronchial glands are enlarged and cut with resistance. Some of them contain calcareous deposits.

THYMI. The thymus gland was barely demonstrable.

SPLEEN. The spleen is about 17 cm. long, 11 cm. broad and 8 cm. thick. It is a light purple in color and is soft and pliable. On section no retraction of the capsule is noted nor can it be stripped from the organ without laceration. The splenic substance is dark purple in color and on section drips blood slowly. The splenic nodules are demonstrable.

KIDNEYS. The left kidney is about 12 cm. long, 9 cm. broad and 6.5 cm. thick. On section the tissue cuts with slight resistance, the capsule does not retract but can easily be stripped from the surface of the organ, striation is demonstable in the cortex. The cortex is narrowed and the tissue is paler than normal.

The right kidney shows practically the same conditions as its fellow and is approximately of the same size.

Both ureters are apparently normal. The bladder is almost empty and shows no macroscopic lesion. The genitals are apparently normal.

LIVER. The liver in situ extends from the fifth rib anteriorally to about 3.5 cm. below the costal margin, and from the right side to a point 10 cm. beyond the median line of the abdomen. The capsule wrinkles on its superior surface when removed. In color the organ is a very dark purple, on section blood drips freely from the cut surface and on removal of the blood the color is uniform throughout. The organ is 38 cm. in its longest measurement, 24 cm. in greatest breadth and 15 cm. in greatest thickness. The gall bladder contains about 15 c. c. of bile and is apparently normal.

PANCREAS. The pancreas is soft and is apparently normal in color and resistance. The organ measures about 12 cm. in length, 3 cm. in width and 1.5 cm. in thickness.

STOMACH. The stomach lies in the usual position and appears to be normal in size. It is practically empty and the mucous membrane shows no gross abnormality.

INTESTINES. The intestinal canal was removed intact, and beginning in the jejunum and extending throughout the ileum and greater portion of the ascending transverse and descending colon are to be found ulcers, deep, sluggish, and having overhanging edges, varying in size from one centimeter to 5 cm. in diameter. At one or two points in the ileum these ulcers are almost annular. The intestines contain very little fecal matter. They were only partially emptied before being sectioned, and were not carefully cleansed before being sent to the laboratory for detailed examination.

The brain and spinal cord were not removed. The organs could not be weighed.

PATHOLOGICAL DIAGNOSIS. Widely distributed pulmonary tuberculosis with the formation of many cavities, widely diffused broncho-pneumonia, hypostatic pneumonia of both bases, extensive tubercular ulceration of the intestines, chronic congestion of the liver, ischio-rectal abscess.

Sections of skin showing induration were removed from the outer portion of the right lower leg, from the lobes of each ear and from the left cheek below the malar bone, for histologic study. Blocks of tissue were removed in duplicate from lung, heart, liver, spleen, kidney and pancreas and placed in 50 per cent. alcohol and 5 per cent. formaldehyde solution respectively. The entire left lung and these tissues were sent to Dr. Herbert Fox for accurate study in the laboratory and for preserving. All other tissue was replaced preparatory for burial.

Note.—The clinical report of this case can be seen by referring to the Report of the Commisioner of Health for the year 1907, pages 28 and 29.

PATHOLOGICAL REPORT ON THE SPECIMENS SUBMITTED, FROM MOCK SEM, A CHINESE LEPER.

D. Rivas, Bacteriologist.

No. 2,350. Philadelphia, January 14, 1909.

A specimen, received from State Health Department, December 28, 1908.

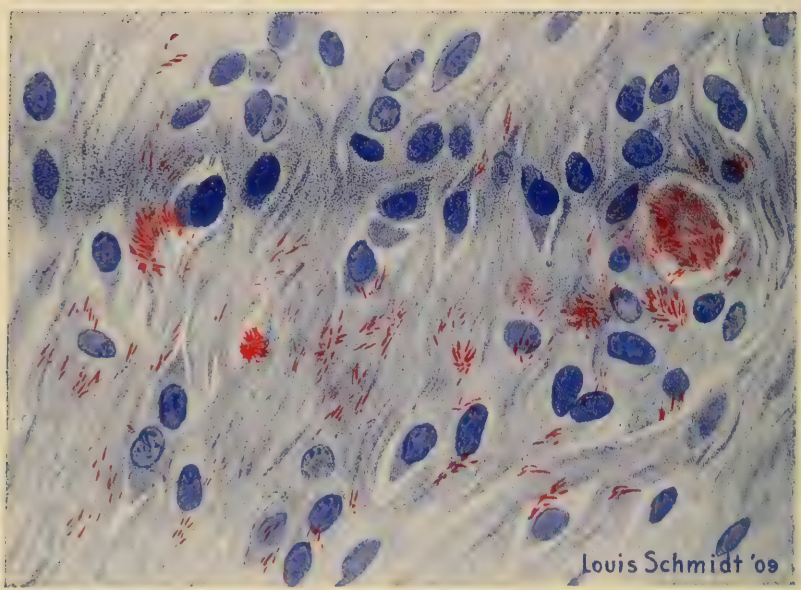
Source. Autopsy Material.

Name and address of patient, Mock Sem, a Chinese leper segregated by State Health Department, near Harrisburg, Pa.

Diagnosis: Leprosy (skin); tuberculosis of lung, liver and spleen; cloudy swelling of liver and kidney.

ALLEN J. SMITH.

In communications with reference to this specimen, please mention above number.



Section of Nodule from Ear; Drawing from a Portion of Thickened Corium, Showing Lepra Organisms,—X 1200.

GROSS AND MINUTE APPEARANCES.

The subject of this case, a young Chinaman, aged from 25 to 30 years, is believed to have been leprous when he first came into this country three or four years before his death. He came from China into British Columbia originally and managed to slip into the United States, as nearly as can be ascertained, by shipping in a coasting vessel and landing in San Francisco. He at once made his way to New York City where undetected he worked for a time in a restaurant. Thence he came to Harrisburg, where he was working as a restaurant waiter when he was detected as a leper. The city authorities are said to have sent him to Baltimore, but he at once returned and for a time remained in the neighboring town of Steelton, Penna. Then the State Department of Health with the Harrisburg authorities provided a small house of isolation for him. It was recognized at the time that not only was he suffering from a well developed case of nodular leprosy but he was also affected by pulmonary tuberculosis.

After a year to two years of isolation, during which the tuberculosis made rapid progress, he died in December of 1908 from the latter disease.

The lungs were found extensively involved, showing both marked diffuse caseation and chronic ulcerative lesions, with enlarged and caseated bronchial lymph nodes. There was extensive ulcerative tuberculosis of the intestines, the ulcers large, numerous, with thick, overhanging edges, smooth indurated bases and numerous miliary tubercles showing superitoneally in the wall of the intestine at the base of each ulcer.

For histological purpose there were sent to the laboratory portions of the lungs, heart wall, liver, spleen and kidney, several cutaneous nodules from the ear lobes and a small bit of thickened and indurated skin from the face.

(1)—A section of a nodule from the ear lobe shows the characteristic features of an active leprous hyperplasia, and with special staining exhibits a vast number of typical leprosy bacilli, in and between the deeper epithelial cells of the epiderm, in large leprous cells and smaller endothelioid cells and in the tissue spaces between the tissue elements of the thickened corium. Some proliferation of the epiderm, with a slight but clearly excessive penetration of the interpapillary portions into the corium has taken place, and at least one epithelial concentric nest was noted quite a distance below the surface. The main elements forming the nodule are in the corium, where the old fibrous matrix is thickly infiltrated by embryonic cells of fibroblastic and endotheloid type, these constituting the bulk of the tissue in most microscopic fields. Scattered mast cells lymphocytes and small plasma cells, and occasional large endothelioid cells ("lepra cells"), and occasional polynuclear leucocytes (some eosinophilic) are encountered.

In the skin of the face the process is evidently older; the corium is thickened largely by a fibrosis, with much smaller number of the infiltrating cells mentioned in connection with the preceding section. The epiderm shows a more definite penetrating growth, at places exhibiting slender root-like extensions into the corium which often unite into a rather fine reticulum just under the major part of the cuticle, reminding one of Unna's reticulate type of epithelioma, and occasionally showing well developed epithelial pearls. With these differences, however, the general characteristics are the same.

(2)—Sections of bits of pulmonary tissue all show tuberculous changes, ranging from typical miliary tubercles to rather large conglomerates with extensive caseation. For the rest catarrhal changes, hyperaemia and oedema with occasional foci of suppuration in and about bronchioles make up the general picture.

(3)—*Wall of Heart:* Epicardium missing from sections examined. No alteration of endocardium. Myocardium somewhat congested, and the fibres rather loosely separated from each other, probably by an oedema. The fibres themselves are

typically rather slender; but show no loss of striation and no pigmentation. The nuclei are as a rule well stained and clear; are for the most part of relatively small size. No fibrosis of the tissue, and no alteration of the wall of coronary branches caught in the section.

4)—*Liver:* Capsule normal. No overgrowth of Glisson's capsules and no important vascular changes. Liver cells generally rather granular and somewhat swollen, a few showing fatty infiltration appearances. The main feature of the sections examined is in the presence of a number of miliary tubercles, mainly of gray type met here and there both in the perilobular tissue and in the interior lobules.

(5)—*Kidneys:* are not from the sections examined seriously changed. There is a scattered cloudy swelling of the cells of the cortical tubules; and in contrast there are many tubules which show no such alteration. At places the tubules are widely distended by a granular coagulated material within them, and occasionally such material exists in Bowman's spaces. No special interstitial change; but a few of the tufts are more or less fibrosed. There is a moderate capillary injection; blood vessel walls normal.

(6)—*Spleen:* The main feature here is a rather marked diffuse endothelial hyperplasia of the pulp. A few more miliary tubercles have been noted in the tissue in addition. The tissue is moderately hypermic, not pigmented; the Malpighian bodies are of normal size and structure; no important change in the wall of blood vessels; no marked overgrowth of the trabeculae of the organ.

REPORT ON THE EPIDEMIC OF TYPHOID FEVER AT READING, NOVEMBER AND DECEMBER, 1908.

A. B. MOULTON, M. D., Chief Medical Inspector.

On the first of September the Morbidity reports received from Reading showed that Typhoid Fever was unusually prevalent in that city, ninety-one cases having been reported for the month of August, distributed by days as follows. During the first twenty-one days of the month 24 cases were reported. Following this day there was a rapid rise in the number of cases reported:

August 22,	2
August 24,	11
August 25,	7
August 26,	11
August 27,	20
August 28,	3
August 29,	1
August 31,	12

As shown by these figures, the increase was especially rapid during the last ten days of the month, 53 cases being reported during the week ending August 28th. In view of the great increase during the last ten days of the month, a letter was written to the Secretary of the Board of Health of Reading noting this rapid rise in the Typhoid rate, and suggesting the probability of a widely disseminated infection which was being transmitted either through the water or milk supply. We further stated that there was a possibility of a severe epidemic in their city, and requested that they advise us of the steps which were being taken to discover the source of these new cases and the means by which it was being transmitted. At the same time we outlined the method which this Department uses in quelling such outbreaks, and asked them to advise us what measures their Board had taken to prevent the further spread of the disease. Replying to this letter, the Secretary of the Board stated that our communication had been laid before the Board, and that he was authorized to give the following reply:

"That the local health authorities are investigating the water and milk supplies in order to ascertain their bearing on the spread of the disease; that the great majority of the cases are of a very mild type, as stated by the attending physicians and proven by the low mortality, only 11 deaths having occurred during the year 1908 to date, in 170 cases reported, that physicians are really reporting in harmony with your suggestions, and that other recommendations will be followed as far as possible."

At that time the situation was not looked upon with any degree of apprehension by the local Board of Health, and nothing was done other than to have printed in the local paper a request that the people boil all water and milk. No census was taken to determine any common source of infection, and there was no hint of a suspicion on the part of the local Board that the general water supply was infected.

On the 28th of November the Morbidity Reports showed that Typhoid Fever had assumed epidemic proportions in that city, and in a 'phone communication with Mayor Rick, the Department was asked to afford assistance in their endeavors to overcome the epidemic. After a careful review of the situation, the offer was made to the authorities in Reading that if they so desired the Department would take full charge and institute the necessary measures to suppress the epidemic, furnishing the necessary corps of engineers, nurses and physicians required. At a conference between the Mayor, local Board of Health, Select Council, City Solicitor and representatives of this Department, the offer made by the Commissioner of Health was accepted, it being agreed that all orders were to be issued over the signature of the Commissioner of Health and the signature of the local Board of Health; all expenses outside of those

of the officials sent by the State Department of Health were to be borne by the city, these expenses including that for district nurses, printing and such supplies as might be furnished to the poor, the work on the watersheds outside of the city limits being directly under the control of the Department. On the 30th of November Mr. Snow, the Chief Engineer of the Department of Health, and the Chief Medical Inspector, entered on the work of suppressing this epidemic. Following the acceptance of this offer a special meeting of the Board of Health was called, at which time a regulation was drawn up and signed by the President of the Board of Health and the Mayor requiring that premises where Typhoid Fever existed should be placarded. This was necessitated in view of the fact that placarding of premises where Typhoid Fever existed had not been enforced in Reading prior to this time. Your representative was authorized to issue such orders as might be necessary to meet any emergency. Models of warning placards, Typhoid placards, Health Officer and Nurses' cards, orders to milkmen, employers of labor and hotel proprietors were prepared and submitted to the local printers for proofs.

A study was made of the records of Typhoid Fever as reported to the local Board during the year 1908. Their records showed the cases occurring each month as follows:

January,	8
February,	5
March,	9
April,	7
May,	3
June,	9
July,	16
August,	91
September,	94
October,	43
November,	353
December,	286

You will note that only 52 cases had occurred in that city from January to July, inclusive, 220 cases had occurred during August and September. At the time when the correspondence, to which reference is made above, the total number of cases for the eleven months, ending November 30th, were 633, 581 of which occurred between August 1st and November 30th, inclusive, which seemed to indicate that there was an infection of the water supply sometime in the early part of July, the effect of which was fast disappearing in the early part of November, since during the first sixteen days of the

month only 14 cases had been reported. Following this date there was a rapid rise in the number of cases reported, as shown by the following table:

	Cases.
November 17,	2
November 18,	13

This sudden rise in the last half of November seems to show that there was another portion of the infective material introduced into the stream the very last of October or the first of November. As a check upon these reports we went over the years from 1895 to 1897, inclusive, which showed an average number of cases approximating 200 per year, the greatest number of cases usually corresponding to the Fall months. The greatest number for any single year was in 1900, when they had 413 cases, and the lowest number for any single year was in 1897, when they had 139 cases. From these reports it seems that typhoid fever had been endemic in Reading for a number of years.

A telegram was sent to a head nurse to immediately proceed to Reading to take charge of the nurses. A list of the milk dealers and the dairy farms from which their supply was obtained was immediately prepared, and the Health Officers in the districts where these dairy farms were located were ordered to immediately inspect each and every dairy farm to determine whether Typhoid Fever existed upon the premises or had existed upon the premises during the past year. Wherever cases had occurred they were to make a report, giving the date of onset, and date of recovery in each instance, with the precautions that were observed to prevent the infection of the milk supply.

The records in the office of the Board of Health were studied and it was determined that about one-third of all the cases of Typhoid existing in the city came from the thirteenth ward, which was supplied with water from the Maiden Creek Reservoir, and the Chief Engineer immediately began the investigation of conditions on the watershed. A force of men was at once secured, sworn in as Special

Health Officers, and set to work placing warning placards about town, on telegraph poles and in saloons, warning people to boil all water and milk before using for domestic purposes. As soon as this work was completed they were detailed to placard houses where Typhoid Fever existed and make inspections of the outhouses and alleys.

On the head nurse's arrival she took charge of the nursing force and made visits to the homes, determining the needs of the individual families, teaching them how to care for those who were ill. The work was extremely heavy both for the nurses and Health Officers in the first few days owing to the large number of cases reported before the work was commenced.

The following routine procedure with regard to cases was carried out:

Upon receipt of a report of typhoid fever, the name and address is transferred to an alphabetical list, health officer's census card, nurse's information card and case card. In this way the list is cross-indexed both as concerns health officers and nurses, the census and information cards being arranged serially in order of the receipt of the report. The Health Officer immediately visits the premises, secures the information required of him, leaves the circular setting forth the precautions which should be observed in the household, and on leaving the premises posts the placard.

A census of the cases shows that by far the larger majority of all the cases secured or drank water from the Maiden Creek supply, while the milk was secured from 145 different sources, involving some 250 dairy farms, in one instance 29 cases occurred on one man's milk route, and in two others 20 were found on a single route. All of these were in the district supplied exclusively by the Maiden Creek water, where the greatest percentage of cases occurred.

The nurse in whose district the case has occurred visits the household, learns the condition of the patient, the environments of the patient, and the needs and the necessity of subsequent visits. At this visit the nurse is instructed to be extremely careful to make plain the necessity of disinfecting the discharges, and instructs them how to do this properly. If lime is not provided, a note to this effect is made and the lime wagon sent there the following day. The men having charge of the lime wagon secure their supply from the Reading Supply Company, receiving a check for the same. These checks, together with the names of those to whom lime is supplied, the same amount being furnished in each instance, are turned over to the City Controller in order that he may make certain there is no leak, and at all times may know how much lime is being used.

At a joint meeting of the various guilds, churches and the Associated Charities at the Common Council Rooms in City Hall, the head nurse was given full authority to secure supplies from the

various grocers in town whenever needed. At this meeting a considerable sum of money was also raised with which to buy muslin for the making of night clothes, sheets and pillow slips to be used as required. See report of supplies furnished.

On December 7th the watershed was visited by the Chief Medical Inspector and specimens of blood for Widal reactions were secured from Wilmer and Myrl Geary, and also from Eva and Mrs. Leinbach. Mrs. Leinbach showed a positive reaction. The premises of Mr. Moyer, near Fleetwood, were also visited, where a case of typhoid fever exists in the person of his daughter Eva. This case was probably contracted in Reading, as the girl was visiting an aunt of her's, who lives in the infected district, during the last week of October, and has been ill for about three weeks. Mr. Moyer ships some 30 or 40 pounds of milk to the New Jerusalem creamery daily, and besides works there himself. Since there was some probability that he came in contact with the patient, it was considered advisable to order that he cease working at the creamery until the recovery of his daughter and the disinfection of the premises.

As only a small proportion of the houses in Reading are connected with a public sewer, the sewerage being discharged into cesspools or wells, it was deemed advisable to investigate the condition of the outhouses and privies, and for this purpose special officers were detailed by the Mayor, and a house to house inspection was made of all the privies and cesspools, and orders of abatement issued wherever the vaults or pits were found full, overflowing or extremely offensive.

Since the alleys in this city belong to the abutting property owners, and in many instances are in very insanitary condition, it was deemed advisable that they should be inspected at the same time. Along these alleys run small gutters, which empty into larger gutters at the sides of the street, and finally terminate in manholes, which connect with a storm sewer. These various surface drains might be called open sewers, since all the wash-water, both from the kitchen and laundry, finds its way into them.

The following tables will be found interesting. Of the 924 cases which occurred during 1908, among which are included those occurring in the epidemic during November and December—with few exceptions and in these few exceptions there was a question of doubt—the entire number secured water either constantly or at times in that section of the city supplied by water from Maiden Creek—494 males and 430 females. Grouped in five-year periods their ages were as follows:

0 to 5 years,	26
5 to 10 years,	117
10 to 15 years,	140
15 to 20 years,	141

20 to 25 years,	121
25 to 30 years,	81
30 to 35 years,	81
35 to 40 years,	45
40 to 45 years,	32
45 to 50 years,	32
50 to 55 years,	12
55 to 60 years,	12
60 and over,	5
Not given,	94

Of occupations they were grouped as follows:

Professional,	37
At home,	215
Domestics,	20
School children,	215
Laborers,	115
Employees in stores,	42
Railroad Employees,	60
Mill hands,	36
Factory employees,	127
Not given,	57

Of this total 743 were treated at home and 158 were treated in hospitals. 106 of these premises were connected with the sewer, 159 with cesspools, while the others had outside dirt closets.

During the months of November and December there were 31 deaths from typhoid fever, showing a case death rate for these two months of approximately 5 per cent.

Milk was supplied to these patients by 136 milkmen. The largest number of cases occurring in any one milk route was 29, while 73 of them had each only one patient on his route.

Of 426 patients treated at home, 390 were nursed by members of the family, 20 by experienced nurses and 16 by trained nurses.

In 583 cases a special study was made by the visiting nurses with regard to the disinfection of the discharges, and it was found that lime was used by 196, chloride of lime by 243, carbolic acid by 67 while 25 made no pretense of disinfection, and 52 gave no outline of the method pursued. Where carbolic acid was used, and in some instances where chloride of lime was used, such small quantities were employed that the effect was practically nil. Disinfection was allowed to go on for a few minutes by 80, and one-half hour by 117, one hour by 112, and an indefinite period, which varied widely, by 197.

The number disinfecting dishes, 248; by simply boiling, 245; by the use of chloride of lime, 3. The number not disinfecting dishes, 151; number giving no satisfactory reply, 284. The number of

patients using boiled milk, 5; uncertain, 329. Number of patients using boiled water, 366; number not using boiled water, 8; unable to determine, 309.

In a few instances where a case of Typhoid Fever occurred in families, they maintained that they had been boiling both water and milk since the outbreak of Typhoid Fever in September, and they further stated that the patients had not drank water or milk away from home.

Since cases of Typhoid Fever occur almost constantly in Reading, and as there are very many parks and picnic grounds and small camps, where the populace assemble on Sundays and holidays for social gatherings, the danger of these local water supplies becoming infected is great, especially when we remember that it is claimed that one per cent. of typhoid patients harbor the germs of this disease in their system and pass them off in the excreta for long periods after the clinical systems have ceased. Special care was enjoined upon the local health authorities and the populace to safeguard these local springs and streams in order that the possibility of infection may be reduced to the minimum

REPORT OF THE NURSE IN CHARGE.

The following is a report of the work done by the District Nurses during the Typhoid Fever epidemic in Reading in the fall and winter of 1908:

The city was divided into districts, one nurse assigned to each district, eight nurses being employed. The total number of cases reported was six hundred and seventy-seven. Of this number ninety cases were found to be of secondary origin. Thirty deaths occurred.

The nurses visited the homes of each patient. Some had trained nurses, others competent caretakers, while many were transferred to the various hospitals. After a thorough canvass of the city, which included instructions in the various households, where other than trained help were caring for the patient, sixty-eight families were found to require the services of the District Nurses. The patients were visited once or twice daily, or oftener, as the needs of the patient demanded. Besides the actual care of the patient, the nurse instructed a member, or members, of the household just what to do and how to care for the patients between the times of her visits. We impressed on these the importance of isolating the patient, absolute cleanliness, and instructions were given how to properly disinfect the excreta, bed and body linen, and dishes used by the patient, etc., excreta, bed and body linen, and dishes used by the patient, etc., etc.

Many families having competent caretakers, but worn out by the long vigil, secured an occasional night's rest by the nurse remaining with the patient during this time. Seventeen families received such service. One family having seven patients (five of these were in a precarious condition and could not be removed to the hospital) required the entire attention of two nurses. Prior to the arrival of the nurses in the city the mother of this family died. The father being the only member escaping the disease, tried to be nurse and housemaid. The distress of this family and of many others who were found unable to secure the many extras incident to a siege of this kind—many of the afflicted ones were the wage-earners, others had been out of employment for a long time—prompted me to lay these facts before Mayor Rick and members of the Board of Health, suggesting that the Mayor call a meeting of the various church and charitable organizations, needlework guilds, etc., asking them to raise ways and means to meet the demands of the needy poor. With great promptness the Mayor called a meeting of the ladies from the various societies. These responded quickly and in a very substantial manner. Sufficient funds were raised at this meeting to purchase supplies, and a committee was appointed to take charge of the distribution of same under my direction. This work progressed in a very satisfactory manner. Through this system of relief ninety-six families were supplied with bed, bedding and wearing apparel. One hundred and ten patients received sick-room supplies, such as alcohol, hot-water bags, chloride of lime, etc., etc. These also received delicacies when convalescent and their families were supplied with general groceries. Fifty-six were supplied with coal, amounting to one hundred and twelve tons; twenty-seven supplied with milk, amounting to fifty-one quarts daily.

Each day found the committee at the post of duty and no delay was occasioned in filling the wants of the needy.

The epidemic occurring during the Christmas Holidays, many of the afflicted families with children to whom Christmas would have passed without any sign of a Holiday, found cheer through the generosity of some citizens. These subscribed to the amount of one hundred dollars. This amount was expended for toys, books, candies, etc. One hundred and seventy-six children were thus made happy. A merchant of the city tendered his wagon and a real Santa Claus to distribute the gifts. The B. P. O. E. supplied fowl to twenty-three families for Christmas dinner. Members of the Needlework Guild made all the garments distributed. The United Traction Company supplied the nurses with free transportation.

The total amount of money received by contribution toward the general relief fund amounted to $793.25; the total amount of money expended to cover expenses of same, $792.87. The one hundred dollars for toys was a separate item.

Letters of thanks were sent to those co-operating in the combatting of this epidemic. The nurses, through their indefatigable efforts, did much to relieve the suffering of those afflicted, and went about their work in a cheerful manner, always ready to respond to a call at any time. Besides the many duties of caring for the sick, they followed up the work of the Health Officer, kept check on the distribution of lime, reported condition of cesspools, and the general sanitary condition of premises. Milk supplies were carefully looked after. The total number of visits made by the nurses was fourteen hundred and forty-seven. Total number of baths given, seven hundred and twenty.

Respectfully submitted,

ALICE M. O'HALLORAN,
Nurse in charge.

OFFICE OF BOARD OF HEALTH.

Reading, Pa., December 1, 1908.

Dear Sir: You and your employees are hereby ordered to discontinue the delivery of milk in bottles or such containers as are again collected for use until otherwise ordered by the Board of Health.

SAMUEL G. DIXON,
Commissioner of Health.
WILLIAM RICK,
Mayor.
JOHN BECKER,
President Board of Health.

Direct inquiries to the Board of Health, City Hall.

OFFICE BOARD OF HEALTH.

Reading, Pa., December 1, 1908.

Dear Sir: Owing to the existence of typhoid fever in our city, you are hereby ordered to furnish to your employees for drinking purposes only such water as has been boiled for at least twenty minutes.

SAMUEL G. DIXON,
Commissioner of Health.
WILLIAM RICK,
Mayor.
JOHN BECKER,
President Board of Health.

Direct inquiries to the Board of Health, City Hall.

DIVISION OF VITAL STATISTICS.

WILMER R. BATT, M. D., *State Registrar.*

MORTALITY.

One hundred and twelve thousand two hundred and forty-six (112,246) deaths, exclusive of still-births, were registered during the calendar year. The death rate was 15.7 per 1,000 of population; a decrease of .8 in rate and of 3,723 in total deaths as compared with the previous year. When applied to the increased population of the State, this death rate represents a decrease of 5,519 deaths in 1908, as compared with 1907.

This rather remarkably low death rate in Pennsylvania was shared by other States composing the registration area of the United States, and indicates a prevailing absence of fatal epidemics, as well as an abatement of some of the ordinary causes of mortality throughout the country.

From the following table showing the death rates for the registration area, and for each of the individual States composing the same, it appears that the death rate for the entire area decreased 1.1 per 1,000 of population, between the years 1907 and 1908.

The rate for 1908, however, includes the States of Washington and Wisconsin, which were added to the registration area for that year, both of which have death rates considerably lower than the average for the registration area.

The average death rate for 1908 for the fifteen States included in the registration area in 1907, was 16.0.

COMPARISON OF DEATH RATES OF THE STATES COMPOSING THE REGISTRATION AREA FOR THE YEARS 1906, 1907, 1908.

	1906.	1907.	1908.
Average rate for registration states,	16.1	16.4	15.3
California,	17.4	18.6	18.4

Washington,	----------	----------	14.8
Wisconsin,	----------	----------	11.6

DEATHS BY MONTHS AND QUARTERS WITH CORRESPONDING ANNUAL RATES PER 1,000 OF POPULATION.

	By Months.		By Quarters.	
	Deaths.	Rates.	Deaths.	Rates.
January,	11,620	19.2		
February,	10,639	18.7	32,737	18.4
March,	10,478	17.3		
April,	9,365	15.9		
May,	8,455	13.9	25,486	14.3
June,	7,666	13.1		
July,	9,534	15.8		
August,	9,708	16.0	28,241	15.7
September,	8,999	15.4		
October,	8,428	13.9		
November,	8,526	14.5	25,782	14.4
December,	8,828	14.6		

The month of January furnished the highest death rate, and in all of the months in the first quarter the rates exceeded those of 1907. In the remaining months the rates were all below the corresponding rates for the previous year with the exception of November, in which the rate was greater by .1.

Of the total deaths, 60,861 occurred to males and 51,385 to females, giving a death rate per 1,000 of each sex of 16.8 for males and 14.6 for females.

The death rates of children under 15 years of age show a slight increase over 1907, while the rates at all subsequent age periods show a decrease. In like manner the percentage of deaths in each age period to the total at all ages shows a slight increase in the ages less than 15 years and a decrease at subsequent ages.

COMPARISON OF DEATH RATES AT CERTAIN AGE PERIODS FOR THE YEARS 1906–1908, INCLUSIVE.

95 years and over,	162	49	113	.1	.09	.2	43

The death rate per 1,000 of native population was 14.7; of native males, 15.5 and of native females, 13.8.

The death rate per 1,000 of foreign population was 20.1; of foreign males, 21.2 and of foreign females, 19.8.

It would thus appear in comparison with the year 1907 that a reduction of the general death rate was influenced by the decrease of deaths among the foreign population, and particularly among foreign males. This would seem to be further borne out by a reference to the general tables in which it will be found that there is a decided reduction in deaths of males from violence, including those industrial accidents in which the foreign males are so frequently involved (mines, mills, quarries, railroad, etc.), as well as in those causes of death which are frequently influenced by male occupations through exposure, etc.

At the same time it must be remembered that the year 1908 was one of severe industrial depression throughout the State and that many males of foreign birth returned temporarily to their native homes. Therefore, there is a very strong probability that the foreign death rate based upon the estimated population appears lower than it really was. Just how much the status of foreign population was

disturbed by emigration during the year will not be ascertainable until the census of 1910. It will be noticed that the death rate of foreign females, whose number is much less likely to be affected by temporary emigration, remained practically the same as during the previous year.

Of the individual causes of death which show decided declines, the most prominent ones in addition to violence are typhoid fever, tuberculosis, diphtheria and pneumonia.

A comparison of the death rates for the several population groups with similar rates for the previous years (1906 and 1907), shows that there was a decrease in each of the nine groups, with the exception of group five (cities and boroughs of between 10,000 and 25,000 population), and group seven (boroughs of between 2,500 and 5,000 population).

It will be noted that during the years 1906 and 1907 Pittsburg appears in group two, and for the year 1908 in group one. This change became necessary through the increase in population arising from the consolidation with the city of Allegheny, which ceased to be a separate registration district on January 1, 1908.

In considering the general death rates for individual municipalities of comparatively small populations, it must be noted that the apparently high death rates in certain places are greatly augmented through deaths in hospitals and other institutions located within their limits whose inmates are recruited from a large surrounding territory, or perhaps, from the entire State. As an example, Norristown presents a high death rate, which is contributed to by the deaths in a large State Hospital for the Insane, and also by deaths in a Hospital which receives patients from quite a large area beyond its corporate and population limits.

For this reason, general death rates must be used with caution. It is hoped with the revised statistics, which should be available from the Federal Census of 1910, to present death rates for that year for all of our principal cities and boroughs which have been corrected so far as the deaths of non-residents are concerned, and also so far as distribution of population by sex, age periods and nativity may influence them.

TYPHOID FEVER.

Two thousand four hundred and fifty (2,450) deaths from this cause occurred during the year, a decrease of 1,088 as compared with 1907. The death rate per 100,000 of population fell from 50.3 to 34.3 during the same period.

The average rate of the registration States declined 4.7 between 1907 and 1908, and among the individual States 7 show increased and 8 decreased rates.

The total decline in the average rate for the three year period for the registration area was 7.2 and in Pennsylvania 22.2.

By reference to the morbidity statistics it will be noted that 15,157 cases of typhoid fever were reported during the year; the case rate mortality, therefore, was 15.5 per cent.

Pennsylvania's past record so far as typhoid fever is concerned has been admittedly bad, not only spasmodically bad, as illustrated by Plymouth, Butler, Scranton and numerous other smaller epidemics, but consistently and constantly bad.

In view of this fact the greatly decreasing death rate is a subject for congratulation to the people of the State.

The actual decrease in point of numbers does not truly represent the saving of life. While the deaths from typhoid fever were actually 1,088 less in 1908 than in 1907, had the death rate of 1907 existed in

1908, there would have been 3,590 deaths in place of 2,450, and likewise, if the death rate of only two years ago had prevailed, there would have been 4,029 deaths.

The same rule applies, of course, to other diseases and indicates the necessity of applying past and present death rates to the increased population in estimating the actual reduction in given causes.

A comparison of the death rates from typhoid fever per 100,000 of population for the States composing the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	31.6	29.1	24.4
California,	39.6	32.5	31.4
Colorado,	56.0	63.7	47.4
Connecticut,	22.1	20.5	18.5
Indiana,	35.9	34.6	32.7
Maine,	18.5	17.7	20.8
Maryland,	40.5	40.3	38.9
Massachusetts,	16.1	12.9	16.7
Michigan,	27.8	22.7	25.9

November,	7.8	9.7	9.3	8.7	8.3	7.7
December,	11.6	7.8	7.5	10.0	8.2	8.0

The diagram showing the deaths from typhoid fever by months in comparison with the preceding two years will illustrate the very general and uniform decline of this disease throughout the State, and at the same time indicate the continued tendency of the disease to increase in the late summer and early autumnal months.

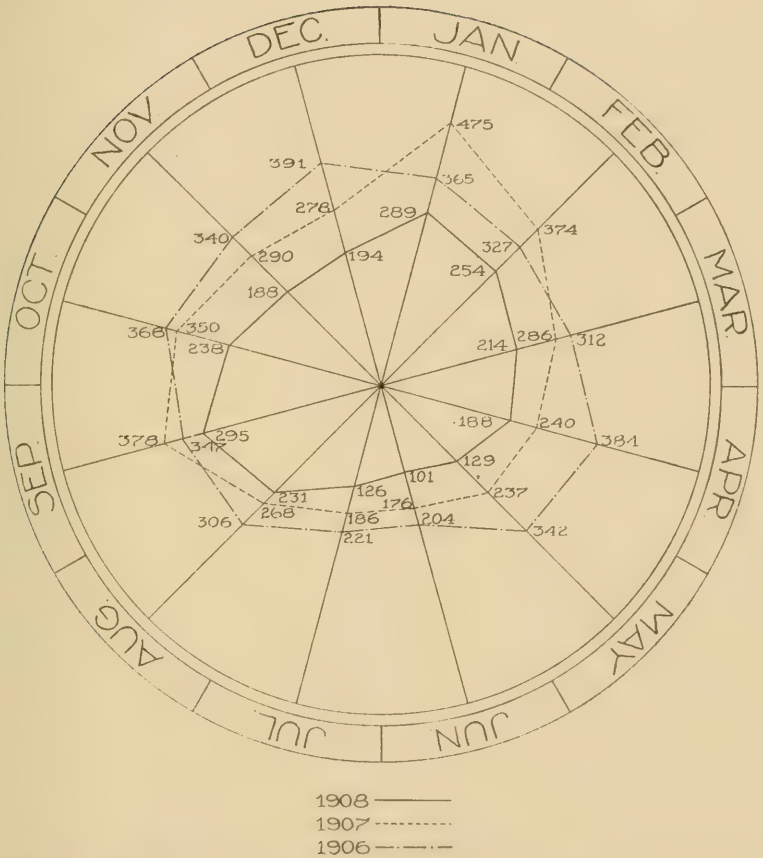

Diagram Showing the Comparative Mortality from Typhoid Fever by the number of Decedents for Each Month for the Years 1906, 1907 and 1908.

The chart further shows by the absence of any sudden variations that no localized epidemics occurred during the year.

In the following table the deaths by age periods for 1908, in comparison with the preceding two years, show a decrease in every quinquennial period up to the eightieth year.

The table also shows the tendency of this disease to attack those in early adult life, reaping its greatest harvest of deaths between the ages of 15 and 35 years.

DEATHS FROM TYPHOID FEVER BY SEX AND AGE PERIODS FOR THE YEARS 1906-1908, INCLUSIVE.

New Castle,	67.2	West Chester,	121.2
Norristown,	45.4	Wilkinsburg,	41.9
Oil City,	46.3	Williamsport,	46.6
Philadelphia,	35.5		

DIPHTHERIA.

One thousand nine hundred and seventy (1,970) deaths occurred from this cause. The death rate per 100,000 of population was 27.6, a decrease of 168 in number of deaths and of 2.8 in the death rate as compared with the previous year.

The average death rates from this disease show a continued decrease in the registration area, although the rates in several of the States are slightly higher in 1908 than in the preceding year.

As an evidence of the efficiency of antitoxin, to the use of which during the past fifteen years the reduction in the death rate of diphtheria is very largely due, it is well to recall that in 1890 in the registration area of the United States the death rate per 100,000 of population was 97.8, and that this rate applied to Pennsylvania for the year 1908 would have given 6,980 deaths in place of the 1,970 which did occur.

A comparison of the death rates from diphtheria per 100,000 of population for the States composing the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	26.9	25.0	22.9
California,	14.3	22.3	22.4
Colorado,	15.1	21.5	28.4
Connecticut,	27.4	24.9	19.3
Indiana,	14.9	12.7	11.7
Maine,	16.2	16.7	14.1
Maryland,	25.7	15.3	13.7
Massachusetts,	25.4	24.9	24.3
Michigan,	18.1	15.9	13.1
New Hampshire,	21.0	22.2	24.3
New Jersey,	31.0	30.8	23.4
New York,	32.7	30.5	28.3
Pennsylvania,	35.2	30.4	27.6
Rhode Island,	25.7	24.8	29.5
South Dakota,	12.2	16.8	21.8
Vermont,	19.7	10.5	11.3
Washington,	----	----	35.4
Wisconsin,	----	----	17.9

DEATHS FROM DIPHTHERIA BY MONTHS.

	1906.	1907.	1908.
Total,	2,438	2,138	1,970
January,	266	259	221
February,	213	165	207
March,	205	145	173
April,	159	139	135
May,	157	125	92
June,	85	99	95
July,	89	82	84
August,	116	118	108
September,	210	167	154
October,	318	267	225
November,	308	276	242
December,	312	256	246

The percentage of deaths to reported cases, or the case rate mortality by months, shows but a slight variation in the malignancy of the disease at different seasons of the year, the rates for May and June, two of the lowest months in point of deaths, being directly comparable with November and December, the two highest months. The first quarter of the year, however, shows an average rate rather higher than any other quarter:

CASE RATE MORTALITY BY MONTHS.

	1906.	1907.	1908.
Average,	22.4	20.3	15.7
January,	25.5	23.6	20.2
February,	24.0	20.0	21.7
March,	23.9	18.8	17.1
April,	22.6	18.8	20.1
May,	22.1	21.7	13.7
June,	15.4	17.9	15.5
July,	20.3	17.3	13.5
August,	27.3	19.8	18.3
September,	21.1	20.9	13.7
October,	20.0	20.7	12.1
November,	21.1	18.7	13.9
December,	25.6	19.6	15.6

The following table shows that while 95.3 per cent. of all deaths occur under 15 years of age, no single quinquennial age period from birth to 75 years is free from this cause of mortality.

SCARLET FEVER.

Deaths from scarlet fever numbered 1,217, an increase of 560 as compared with the previous year. The death rate per 100,000 of population increased from 9.3 in 1907 to 17.1. During the same period the death rate in the registration area increased from 9.6 to 13.0. This increase was most noticeable in the contiguous registration States of New York, New Jersey and Pennsylvania, in which the rates are rather closely approximated, indicating the presence of this disease in an epidemic form over that territory.

The case rate mortality in 1908 was 8.4.

A comparison of the death rates from scarlet fever per 100,000 of population for the States composing the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	7.5	9.6	13.0
California,	3.2	4.4	6.3

MEASLES.

Deaths from measles numbered 1,215, an increase of 501 as compared with 1907. The death rate per 100,000 of population was 17.0, an increase of 7.2. The death rate increased in the registration area 1.1 during the same period. The extent to which this disease prevailed during the year may be partially understood by reference to the morbidity tables, from which it will be noted that 37,981 cases of this disease were reported to the Department of Health during the year. As large as this number was, it is very probable that many cases were unreported owing to the slight regard in which the disease is held by many parents who do not employ skilled medical attention in its treatment.

A comparison of the death rates from measles per 100,000 of population for the States comprising the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	13.2	9.9	11.0
California,	10.1	10.9	5.2

WHOOPINGCOUGH.

Deaths from this disease numbered 1,264, a decrease of 23 as compared with 1907. The death rate per 100,000 of population decreased .6 during the same period.

The death rate in the registration area of States declined from 11.7 in 1907 to 11.1 in 1908. The greatest number of deaths occurred during the summer months, as in the previous years; 53.7 per cent. of all deaths from this cause occurred to children under one year of age and 95.8 per cent. to children under five years of age.

A comparison of the death rates from whooping cough per 100,000 of population for the States composing the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	16.5	11.7	11.1
California,	5.9	8.4	7.8
Colorado,	15.3	7.8	22.3

TUBERCULOSIS.

Ten thousand two hundred and eleven (10,211) deaths occurred from tuberculosis in all forms during the year, a decrease of 614 as compared with the previous year. All of this decrease is to be found in the deaths from tuberculosis of the lungs, which numbered 8,703, while deaths from tuberculosis of other organs remained exactly the same as in the previous year, 1,508.

The forms of tuberculosis represented with the percentage in each group to total deaths from this cause are as follows:

	Deaths.	Per Cent.
Tuberculosis of lungs,	8,703	85.2
Tuberculosis of larynx,	102	1.0
Tuberculous meningitis	513	5.0
Abdominal tuberculosis,	394	3.8
Potts disease,	110	1.1
Tuberculous abscess,	16	0.1
White swelling,	54	0.5
Tuberculosis of other organs,	117	1.3
General tuberculosis,	202	2.0

The death rate per 100,000 of population from tuberculosis in all forms was 143.6, and of tuberculosis of the lungs 121.9, a decrease of 10.3 for the former and of 10.5 for the latter.

A comparison of the death rates from tuberculosis of the lungs per 100,000 of population for the States composing the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	155.4	155.1	144.7

MORTALITY OF TUBERCULOSIS OF THE LUNGS IN REFERENCE TO OCCUPATION.

In the annual report for 1907, death rates were given for certain occupations and groups of occupations based upon the number of persons employed in each class. Without repeating this table for 1908, which differs but slightly from the table for 1907, it may be interesting to consider this cause of mortality in reference to age and the relative importance of certain occupations in connection therewith.

For this purpose the following data are extracted from the Mortality Statistics of the United States Census Office, and cover deaths from tuberculosis of the lungs throughout the registration area comprising 51.8 per cent. of the entire population of the United States. As evidence that the statistics derived from this source are comparable to Pennsylvania it should be realized that 16.2 per cent., or practically one-sixth of all deaths in the registration area upon which the data are based are contributed by this State.

The economic value of lives lost through tuberculosis of the lungs may be better appreciated when it is considered that 66 per cent. of all deaths from this disease occur between the ages of 25 and 64 years, and that this is the period of life most valuable to the individual and the State. The average age at death from tuberculosis of the lungs was 35.5 years.

Deaths of males from all causes and at all ages in the registration area numbered 375,497, and of these 196,207 or 52.3 per cent., were stated to have a gainful occupation. Deaths of males from tuberculosis of the lungs at all ages numbered 38,055, and of these 29,433, or

77.3 per cent., were stated to have gainful occupations, thus 15.0 per cent. of the deaths of occupied males at all ages were due to tuberculosis of the lungs. Between the age periods, 25-34, the deaths of male wage earners numbered 27,336, and of this number 8,446, or 30.9 per cent. (almost one death in every three), was due to tuberculosis of the lungs.

Between the age periods, 35 to 44, the total deaths of male wage earners numbered 30,632, and of this number 7,453, or 24.3 per cent. (one in every four), was due to tuberculosis of the lungs.

Between the age periods, 45 to 54, the rate was 14.4 per cent., and between 55 and 64 the rate was 7.6 per cent.

From these facts it would seem apparent that the mortality from tuberculosis of the lungs decreases rapidly with advancing years, as the total deaths from all causes increase, while those from tuberculosis decline, thus reducing the proportional deaths from the latter cause. It must be recalled, however, that deaths from other causes than tuberculosis assume a growing importance in the advanced age periods and at the same time the actual population at similar periods decreases.

Thus it will be clearly shown by the following statistics that although the percentage of deaths from tuberculosis to total deaths in the several age periods declines rapidly, the death rate per 100,000 of population living at the several ages remains relatively stationary.

	Total.	25 to 34 Years.	35 to 44 Years.	45 to 54 Years.	55 to 64 Years.
Male population of the United States (1900), over 10 years of age (Registration States),	6,937,288	1,541,280	1,238,393	841,800	538,704
Deaths from tuberculosis,	15,690	4,616	3,507	2,164	1,330
Per cent. of deaths from tuberculosis to total deaths,	100.0	29.4	22.4	13.8	8.5
Death rate from tuberculosis per 100,000 of population at the several age periods,	226.2	299.5	283.2	257.1	246.9

Among females, the proportion engaged in gainful occupations is naturally much smaller than among males, and the earlier age period, 15 to 24, plays a more conspicuous part. During 1908 there were in the registration area 316,077 deaths of females, and of this number 26,065, or only 8.3 per cent., were returned as wage earners. Of the total deaths, 29,321 were due to tuberculosis of the lungs, and of this number 5,511, or 18.8, were assigned gainful occupations.

The following table, while disregarding entirely any consideration of the total number of persons employed in the several groups and occupations, nevertheless shows some extremely interesting and important facts.

Thus we find that of all male bookkeepers, clerks and copyists dying between the ages, 25 and 34 years, 41.9 per cent. die of tuberculosis of the lungs, and similarly that among barbers and hairdressers the proportion is 40.1 per cent., among servants 40.9 per cent., and among boot and shoemakers 44.1 per cent. These figures are important as illustrating the position occupied by tuberculosis of the lungs as a mortality factor at certain ages and in certain occupations as compared with all other causes of death.

Table showing the number and percentage of deaths from tuberculosis of the lungs of males at least 10 years of age engaged in gainful occupations as compared with deaths from all causes at corresponding ages and similar rates for certain age groups, 25 to 65 years, in certain specified occupations. (Registration area).

CANCER.

Deaths from cancer numbered 4,520, an increase of 100 as compared with 1907.

A comparison of the deaths for the three year period, 1906 to 1908, inclusive, according to locality or organ affected, is as follows:

	1906.	1907.	1908.
Total,	4,208	4,420	4,520
Cancer of the mouth,	160	114	177
Cancer of the stomach and liver,	1,620	1,666	1,733
Cancer of the intestines,	440	488	502
Cancer of the female genital organs,	595	640	738
Cancer of the breast,	399	368	452
Cancer of the skin,	160	188	169
Cancer of other or unspecified organs,	834	926	749

A comparison of the death rates from cancer per 100,000 of population for the States composing the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	70.9	73.6	74.6
California,	92.0	95.9	104.2
Colorado,	51.3	55.1	62.7
Connecticut,	80.6	80.1	76.1
Indiana,	53.7	57.1	64.7
Maine,	86.2	101.3	96.4
Maryland,	60.1	60.9	62.9
Massachusetts,	90.3	93.5	93.7
Michigan,	67.6	66.7	72.9
New Hampshire,	89.2	95.8	87.3
New Jersey,	66.1	65.4	67.5
New York,	76.2	78.9	79.5
Pennsylvania,	60.7	62.8	63.3
Rhode Island,	78.3	91.1	83.6
South Dakota,	35.4	38.8	46.2
Vermont,	85.3	99.0	92.2
Washington,	----	----	72.0
Wisconsin,	----	----	65.1

From the above statistics the tendency of cancer to steadily increase is quite evident, but four of the States mentioned showing a decrease as compared with the previous year. The rather large increase noted in the actual number of deaths assigned to cancer of certain specified organs or localities, notably cancer of the female genital organs, is accounted for to a certain degree by the continued effort to secure more definite information on death certificates as to

the exact location of the cancer or the special organs affected. As a result of these efforts it will be noted that deaths from cancer of other or unspecified organs decreased from 926, or 20.9 per cent. of the total in 1907, to 749, or 16.5 per cent., of the total in 1908. We hope that the day is not far distant when the term "unspecified" can be eliminated from our cancer statistics.

DISEASES OF THE NERVOUS SYSTEM.

The total number of deaths due to diseases of the nervous system was 11,372, a decrease of 855 as compared with the previous year. The death rate per 100,000 of the population was 159.3. The death rate per 100,000 of male population was 167.4, and of females 151.0. Apoplexy was the cause of 5,255 deaths, or 46.2 per cent. of the total deaths in this group.

DISEASES OF THE CIRCULATORY SYSTEM.

Deaths from diseases of the circulatory system numbered 11,345, a decrease of 432 as compared with 1907. The death rate per 100,000 of population decreased from 167.4 to 159.0.

Heart disease was responsible for 83.7 per cent. of all deaths in this group. The age periods in excess of 60 years furnished 60.3 per cent. of the total.

DISEASES OF THE RESPIRATORY SYSTEM.

Thirteen thousand nine hundred and twenty-nine (13,929) deaths occurred from diseases of this group, a decrease of 455 as compared with the previous year. The rate per 100,000 of population decreased from 204.5 to 195.1.

Pneumonia was the most important single cause in this group, causing 7,102 deaths as compared with 7,849 in 1907. The death rate per 100,000 of population decreased from 111.6 to 99.5.

A comparison of the death rates from pneumonia per 100,000 of population for the States composing the registration area for the years 1906, 1907 and 1908 is as follows:

	1906.	1907.	1908.
Average rate,	109.5	117.2	96.1
California,	106.9	119.7	104.0
Colorado,	147.7	155.2	155.7
Connecticut,	113.1	128.9	97.5
Indiana,	76.8	76.0	63.4
Maine,	106.4	129.7	111.6
Maryland,	95.6	100.6	86.5
Massachusetts,	121.6	126.5	112.7
Michigan,	74.0	83.8	66.1
New Hampshire,	104.2	112.4	96.0
New Jersey,	132.3	140.9	110.1
New York,	123.4	132.8	103.3
Pennsylvania,	106.9	111.6	99.5
Rhode Island,	141.5	140.6	119.6
South Dakota,	50.9	68.8	78.2
Vermont,	126.4	140.5	113.2
Washington,	----------	----------	83.5
Wisconsin,	----------	----------	69.8

Broncho-pneumonia was responsible for 3,311 deaths, of which 2,668, or 80.6 per cent., were under five years of age.

DISEASES OF THE DIGESTIVE SYSTEM.

Deaths from diseases of the digestive system numbered 16,306, an increase of 269 as compared with the previous year. The rate per 100,000 of population remained practically stationary, 228.4.

Deaths from diarrhoea and enteritis numbered 10,393, and of these 9,026, or 86.8 per cent., occurred in children under two years of age. The increase in the number of deaths from this cause (404) as compared with the previous year may be largely found in the climatic conditions which prevailed during the months of July and August.

DISEASES OF THE GENITO-URINARY SYSTEM.

Seven thousand five hundred and fifty-three (7,553) deaths occurred from diseases of the genito-urinary system as compared with 7,659 for the previous year. The death rate per 100,000 of population decreased from 108.9 to 105.8. Bright's disease and acute nephritis were responsible for 6,346, or 84.0 per cent., of the total deaths under this group.

VIOLENCE.

Nine thousand six hundred and thirty-one (9,631) deaths occurred from violence in all forms during the year, a decrease of 1,235 as compared with the previous year.

The death rate per 100,000 of population decreased from 154.5 to 134.9.

A comparison of the deaths from certain principal forms of violence as compared with the years 1906 and 1907 is as follows:

	1906.	1907.	1908.
Suicide,	780	892	988
Burns and scalds,	847	971	861
Drowning (accidental),	555	566	573
Gunshot wounds (accidental),	149	139	150
Injuries in mines,	983	1,508	1,326
Steam railway injuries,	2,159	2,134	1,457
Homicide,	365	406	365

From the foregoing it will be noted that deaths from injuries on steam railroads show a very material decrease from the preceding years, which is to be largely accounted for by the decline in transportation and the number of persons so employed, incident to the industrial depression, which prevailed during the year. Of the total suicides, 761 were males and 227 were females; 297 employed poison, 287 were by firearms and 180 by hanging. Two suicides were less than 15 years of age. The rate from suicide per 100,000 of population was 13.8.

BIRTHS.

There were registered during the year 194,623 births, exclusive of still-births.

This was an increase of 18,819 over the previous year and an increase in the birth rate from 24.1 per 1,000 of population in 1906 and 25.0 in 1907 to 27.3 for 1908.

As mentioned in the report for 1907, this increase in the number of births does not indicate an actual increase in the birth rate, but does indicate an increased accuracy in the registration of births.

A persistent effort has been made to overcome the difficulties that beset complete birth registration, and the results for the present year show that these efforts have not been without some gratifying results.

The native birth rate increased from 20.4 in 1907 to 21.4, and the foreign rate increased from 49.3 to 58.8 per 1,000 of each population. It was among the foreign population, therefore, that the greatest relative gain was made. This is readily understood when we consider the disproportionate number of midwives who work exclusively among the foreign born and also the large number of children among this class born without any attention other than neighborly assistance. The process of educating such persons as to the existence of registration laws and that such laws must be observed is necessarily difficult.

The excess of births over deaths for the year was 82,377, and while it was impossible in the absence of a census enumeration to determine exactly the actual birth rate of the State, the excess noted when added to the increase by immigration is somewhat closely approaching the total yearly increase of population as estimated by the Federal government.

Of the total births, 100,517 were males and 94,106 females.

There were 2,078 twin births, of which number 1,315 occurred to native mothers and 759 to foreign mothers, while in 4 the nativity of mothers was unstated.

Of triple births there were 17; among native mothers 6 and among foreign mothers 11.

Illegitimate births numbered 4,401, the illegitimate birth rate per 100,000 of population being 61.6. For natives the rate was 62.7 and for foreign-born 53.8.

Table 1 shows the births by sex and months for the entire State, and for all incorporated municipalities over 5,000; also for certain groups of municipalities, and for the rural sections of each county.

Table 2 shows the births for the same areas by age and nativity of mothers.

Table 3 shows the births for the same areas by the nativity of mothers and the number of the child.

Table 4 shows the illegitimate births by localities and nativity of mothers.

Table 5 shows plural births (twins only) by localities and nativity of mothers.

MORTALITY TABLE I.

Deaths by months for all municipalities having over 5,000 population, for groups of municipalities having less than 5,000 population, and for the rural section of each county. (Stillbirths excluded).

THE SUB-DIVISION OF MORBIDITY STATISTICS.

In Charge of WILMER R. BATT, M. D., *Registrar*.

23—17—1908

MORBIDITY STATISTICS.

One hundred and thirteen thousand eight hundred and twenty-five (113,825) cases of communicable diseases were reported to the Department of Health during the year, an increase of 42,961 as compared with the previous year. From the following table it will be noted that this large total increase was due chiefly to measles, scarlet fever, tuberculosis and whooping cough. Measles was epidemic throughout the State, while the increase in tuberculosis was not due to any actual increase in the total number of cases but rather to a more complete reporting by physicians.

TOTAL CASES OF EACH COMMUNICABLE DISEASE REPORTED.

DURING 1906, 1907 and 1908.

	1906.	1907.	1908.
All communicable diseases,	88,320	70,864	113,825

TYPHOID FEVER.

Fifteen thousand one hundred and fifty-seven (15,157) cases of typhoid fever were reported during the year, a decrease of 4,923 as compared with the previous year. Urban cases decreased 6,705 and rural cases increased 1,782.

The following table shows the comparison of cases reported by months for the years 1906 to 1908, inclusive:

TUBERCULOSIS.

Ten thousand four hundred and eighteen (10,418) cases of tuberculosis were reported during the year, an increase of 4,309 as compared with the previous year. Reference to the deaths from tuberculosis will show that the increase in the number of cases reported does not indicate an increase of the disease, but simply a better registration of the living cases.

THE SUB-DIVISION OF MARRIAGE STATISTICS.

In Charge of WILMER R. BATT, M. D., *Registrar.*

MARRIAGES.

Fifty-four thousand three hundred and two (54,302) marriages were recorded during the year, a decrease of 5,941 as compared with 1907. The number of persons married per 1,000 of population was 15.3 as compared with 17.1 for the previous year. The decrease in marriages is a reflex of the industrial and financial depression existing during practically the entire year of 1908. The close association in the fluctuations of the marriage rate with varying periods of general prosperity has been frequently noted. For many years in England it was possible to trace a correspondence between the rise and fall in the marriage rate and the fluctuations in the price of wheat. In late years wheat has apparently lost its position as an index of national prosperity, and the variations in the marriage rate follow more closely the general wage earning opportunities as reflected in a variety of industrial activities.

A decrease in the marriage rate is of considerable statistical significance from the fact that it must have an influence in diminishing the birth rate, and likewise the infant death rate, as well as disturbing not only the increase of population, but distribution of population by age periods.

The average age at marriage of both brides and grooms remained practically stationary. Of the native brides, 67.3 per cent. were less than 25 years of age, and 73.2 per cent. of the foreign brides were of similar age.

Among brides there were 49,670 first marriages, 4,572 second marriages, 59 third marriages, and 1 fourth marriage.

Among grooms there were 48,836 first marriages, 5,367 second marriages, 85 third marriages and 14 fourth marriages.

Of the 4,648 re-marriages among brides, 3,608 had been previously widowed and 1,040 had been divorced.

Of the 5,353 re-marriages among grooms, 4,487 had been widowered and 866 had been divorced.

Table 1 shows the number of marriages in each county of the State by months with totals for the entire State.

Table 2 shows the marriage rate (number of persons married to each 1,000 of the population) for each county of the State for the three years, 1906 to 1908, inclusive.

Table 3 shows the ages and nativity of brides and grooms.

Table 4 shows the percentage of brides and grooms by age periods.

Table 5 shows the percentage of marriages by months.

Table 6 shows the number of marriages by age periods for brides and grooms.

Table 7 shows the ages at which re-marriages occurred among brides and grooms, and how the previous marriages were dissolved.

THE DIVISION OF DISTRIBUTION OF BIOLOGICAL PRODUCTS.

DIPHTHERIA ANTITOXIN.

From the date of the beginning of the Distribution of Diphtheria Antitoxin to the indigent throughout tthe State of Pennsylvania by the Department of Health, in October, 1905, until December 31, 1908, just three years and three months, fifteen thousand four hundred and twenty-nine persons (15,429) afflicted with Diphtheria were treated for cure, and of this number only thirteen hundred and forty-nine (1,349) or 8.74 per cent. resulted fatally.

In addition to the number mentioned that were treated for cure, ten thousand two hundred and fifty-three (10,253) persons, mostly little children who were exposed to the disease, were immunized, and of this number so immunized, only one hundred and sixty-one (161) contracted the disease, and of those who contracted the disease only thirteen died, or a death rate of .00126 per cent.

The total number of cases treated among the indigent throughout the entire State during the year 1908 was 6336, of which number only 542 resulted fatally, showing the low death rate of 8.55 per cent.

The comparison of results obtained for the years 1907 and 1908 will be found in the Summary of Observations Upon the Use of Diphtheria Antitoxin for the Year 1908, on page 395 of this report, and much interesting information in detail taken from the clinical reports received from physicians will be found in the tables beginning on page 398.

While the distribution of Antitoxin by the Department began in October, 1905, the establishment of distributing stations and the appointment of Distributors did not take place until November 4, 1905, when 473 Distributors were appointed at convenient places in every county in the State outside of the cities of Philadelphia and Pittsburg, most of them being duly registered druggists, with the exception of a few physicians and general storekeepers appointed at places where no drug stores could be found.

The number of stations was increased as the actual need for same, after careful investigation, became apparent to the Department, and at the end of December, 1906, numbered 511, an increase of 38 for that year.

The demand for additional distributing stations during the year 1907 became so imperative that the Commissioner of Health felt it his duty to increase the number already established, and December 31, 1907, found us with a total of 529 distributing stations, an increase of 18 over the year 1906.

In this connection it might be well to state that, notwithstanding the additional number of distributors appointed during 1907, the demand became so persistent (the Commissioner of Health having received in 1908 over two hundred communications from physicians and others recommending additional distributing stations at various points throughout the State), it was decided, after careful consideration, to establish still more Distributing Stations, and at the end of December 31, 1908, the total number of Distributors amounted to 569, an increase of 40 over the year 1907. A glance at the map to the left will give the reader a fair idea as to the locations of the distributing stations now existing, and the accompanying list gives the names of the distributors appointed to December 31, 1908.

DISTRIBUTORS OF

DIPHTHERIA ANTITOXIN.

Appointed by Commissioner of Health.

Antitoxin either for curative or immunizing purposes and in appropriate doses may be secured by physicians practicing in this Commonwealth upon their agreeing in writing that no charge of any kind is to be made for the Antitoxin, and that the person or persons for whom it is obtained are indigent in the sense that they cannot procure the necessities of life and at the same time purchase Antitoxin, and also that the physician will send to the Department of Health a full clinical report as specified by the Commissioner of Health.

COMMISSION.

COMMONWEALTH OF PENNSYLVANIA.

DEPARTMENT OF HEALTH.

Division of Distribution of Biological Products.

Know all men by these presents, that .....
residing at ..... in the county of .....
State of Pennsylvania, ha.... this ..... day of ..... 190....
been duly appointed Distributor of Diphtheria Antitoxin, at .....
..... County, Pennsylvania, under the rules of the Department of Health.

(Seal)

.....
Commissioner of Health.

METHOD OF DISTRIBUTION.

After appointment the Distributor is furnished with an initial supply of serum consisting of five packages of 1000 units and five packages of 3000 units, and in about fifteen localities in the State, Distributors are supplied with a stock of five packages of 5000 units of Antitoxin, at the special request of physicians at those points, together with blank forms, stamped envelopes, etc., necessary for its distribution; copies of which forms appear hereafter.

The physician discovering a case of diphtheria anywhere in his locality among the poor has but to go to the nearest druggist who is a Distributor, sign a receipt and secure all the Antitoxin he needs for the treatment of the case or cases he has on hand.

Form P. P. 516.

COMMONWEALTH OF PENNSYLVANIA.

DEPARTMENT OF HEALTH.

Division of Distribution of Biological Products.

INSTRUCTIONS TO DISTRIBUTORS REGARDING THE DISTRIBUTION AND USE OF DIPHTHERIA ANTITOXIN.

In the distribution of Diphtheria Antitoxin there are THREE PRINTED forms which MUST be filled out.

FIRST IN IMPORTANCE, FORM B. P. 517, is known as the Application and Receipt. It is in a small book containing 100 numbered pages—50 white and 50 blue—the white to be signed by the physician

and forwarded to the Department after the amounts of Antitoxin secured by him are properly filled out in the spaces reserved for this purpose; the blue pages, on which the carbon copy is taken, remain in the book for the distributor's own record. A space is especially provided in the lower left hand corner of this FORM B. P. 517 for a statement of Distributor's stock of Antitoxin on hand, the filling out of which space will prevent the distributor from ever allowing his stock of Antitoxin to become ENTIRELY exhausted, as a careful examination is made of each Form B. P. 517 immediately upon its receipt, and if the stock is found to be low, additional supply is at once forwarded. This avoids the expense of telegraph and telephone messages to the Department for additional stock.

A physician having a case of Diphtheria among the poor should immediately APPLY to the nearest Distributor, SIGN a RECEIPT Form B. P. 517, and secure all the Antitoxin he needs for the treatment of the case. He agrees, as you will see by the Application and Receipt, to return to the Distributor all unused Antitoxin WITHIN TEN DAYS after securing the same.

Our experience teaches us that the Distributor should require physicians to sign for the Antitoxin BEFORE securing same, if at all possible, because when they send for it they often fail to come in and receipt for same for several days and sometimes never sign for it at all.

SECOND, FORM B. P. 519, is the little slip found wrapped around the outside of the box of Antitoxin. It is to be filled out by the physician, with the patient's name and address, date of use, physician's signature and address, distributor's signature and address, and MUST, when returned to the Distributor, be forwarded by him to the Department of Health, together with the above mentioned Application and Receipt, Form B. P. 517, in the printed stamped envelopes furnished to the Distributor.

THIRD, FORM B. P. 518, is the Clinical Report, and is found inside the box of Antitoxin. The physician fills this out, signs and returns it to the Department at the termination of the case. The Distributor has NOTHING WHATEVER TO DO WITH THIS FORM.

SPECIAL NOTICE, FORM B. P. 524 (copy of which is enclosed herewith), contains instructions relative to sale of Antitoxin belonging to the State supply ONLY in cases of emergency. It sometimes happens the private supply of the Distributor becomes exhausted at a time when a call may come from a person well able to pay for same. In such cases the Distributor is allowed to take Antitoxin from his State supply with the distinct understanding that it MUST BE IMMEDIATELY REPLACED BY PURCHASE from Messrs. H. M. Alexander & Co. at their market price, and in communicating with them in regard thereto the Distributor should not fail to make it clear the exact number of either 1000, 3000 or 5000 unit packages of

STATE goods being replaced. In this connection I would state that the same record is required by the Department for goods that are sold and taken from the State supply as is made for indigent cases, the only difference being that the word "SOLD" must be written across the face of all these records for identification here.

Our distributing agents, Messrs. H. M. Alexander & Co., Marietta, Pa., have been instructed to forward you an INITIAL supply of 5 packages of 1000 units and 5 packages of 3000 units of Antitoxin, and Distributors should bear in mind that an additional supply will be furnished immediately upon notification that this stock is NEARLY exhausted, which notice can be made by simply filling up the space in the lower left hand corner of FORM B. P. 517, specifically provided for a statement of stock on hand.

Should an epidemic of Diphtheria break out in your locality, when a large quantity of Antitoxin might be needed at once, you are then authorized to telegraph, C. O. D. (using the enclosed code), or to telephone, reversing charges to this office for the necessary additional supply.

SAMUEL G. DIXON, M,. D.
Commissioner of Health.

B. P. 517.

COMMONWEALTH OF PENNSYLVANIA.

DEPARTMENT OF HEALTH.

APPLICATION AND RECEIPT FOR DIPHTHERIA ANTITOIN.

.....190..

I hereby acknowledge the receipt of the following named amounts of Diphtheria Antitoxin; for use in the family of .....
.....packages containing 1,000 units. Laboratory Nos., ...
.....packages containing 3,000 units. Laboratory Nos., ...
.....packages containing 5,000 units. Laboratory Nos., ...
from .....Distributor, Address, ...
in the name of the Department of Health. I hereby certify that the person or persons mentioned for whom this Antitoxin is furnished for the treatment of Diphtheria are indigent in the sense that they cannot procure the necessities of life and at the same time purchase Antitoxin. I agree to make no charge for it directly or indirectly, and if unused, to return to the Distributor within ten days; also to mail to the Department of Health, immediately upon termination, a clinical report for each case, on the blanks furnished for this purpose.

We have in stock at this time:

.....packages of 1,000 units. .....
.....packages of 3,000 units. (Physician's signature.)
.....packages of 5,000 units. .....
(Address.)

.....
(Distributor's signature.)

.....
(Full Address.)

with blue stub for Distributor's record; being Application and Receipt to be signed by the physician upon making application to the Distributor for Antitoxin for use on indigent patients in his locality found stricken with the disease, which gives the exact number of packages of Antitoxin—1000 units (immunizing) and 3000 and 5000 units (curative) taken by him, and which is forwarded to the Department with Form No. 519, mentioned below. The blue stub is for the Distributor's record of Antitoxin issued.

Distributor's name, ... Signature, ...M. D.

Address, ...

The above is the Clinical report which gives the complete medical history of the case from the beginning of treatment to either recovery or death, and which is to be signed by the physician and forwarded to the Department.

Form B. P. 519.

..... Units.	COMMONWEALTH OF PENN'A. DEPARTMENT OF HEALTH.
Manufacturer.	Diphtheria Antitoxin, ...Units.
.....	Manufacturer, ...Laboratory No.....
Laboratory No.	Patient, ...Address,.....
Date within which the unopened vial or attached slip must be returned to Distributor, ...	Date of use, ...
.....	Physician's signature, ...
	Address, ...
	Distributor's signature, ...
	Address, ...
	This slip when returned to Distributor must be forwarded to the Department of Health, together with the application for the same.
	SAMUEL G. DIXON, Commissioner.

This slip is found placed around the outside of the packages of Antitoxin, and is to be filled out by the physician using same; giving name of patient and address, date of use, physician's name and address, distributor's signature and address, and to be forwarded to the Department with Form B. P. 517, above mentioned.

These slips, Form B. P. 519, are filled out for 1000 units, immunizing, and 3000 and 5000 units, curative treatment, respectively; each slip of Form B. P. No. 519 representing one package of 1000, 3000 or 5000 units strength; having also printed thereon the Laboratory number of the package of Antitoxin produced by the manufacturer.

The three forms above mentioned, B. P. 517, 518 and 519, when properly filled out, make a complete record of each case of the distribution and use of Diphtheria Antitoxin issued by the Department of Health to the indigent throughout the entire State of Pennsylvania.

SUMMARY OF OBSERVATIONS UPON THE USE OF DIPHTHERIA ANTITOXIN IN PENNSYLVANIA FOR THE YEAR 1908.

CURATIVE TREATMENT.

The statistics compiled as taken from the clinical reports received from physicians covering the curative treatment of diphtheria among the indigent for the year 1908, show a slight increase in the death rate over the year 1907, and also show that physicians throughout the State did not as strictly take heed, as they did in the previous year, to the urgent requests of the Commissioner of Health given from time to time, to use Antitoxin as early as possible after onset of the disease and in larger doses.

It will be shown by a comparison of Table No. 1 for the year 1908 with the same Table for 1907, that 6,336 persons were treated for diphtheria with but 542 deaths (an increase in number treated, of 1,065 over the year 1907), and that the deaths have been but slightly increased in the year 1908 over the previous year. It will also be noticed in Table No. 1 for 1908, compared with 1907, in the treatment of cases of diphtheria within the first twenty-four hours of onset, that the death rate, though brought to the very low percentage of 6.53 per cent. is slightly increased over the death rate in the previous year. In each succeeding day of treatment after onset

an increase in the death rate naturally appears until the seventh day is reached, when, contrary to what might be expected, the death rate is found to be only 19.51 per cent., much lower even than the results obtained in the previous, or sixth-day-treatment.

In Table No. 2, "Showing Results of Treatment of Diphtheria with Antitoxin with Relation to Sex and Age," it will be seen that 2,892 males and 3,444 females were treated in 1908 as compared with 2,493 males and 2,778 females in 1907. It also reveals the fact that in both years the greatest number of cases of diphtheria occurred in children of both sexes between the ages of five and nine years; the females predominating in 1908, with 1,261 to 1,070 males.

In Table No. 3, showing result of treatment of diphtheria with Antitoxin according to period of initial treatment after onset and age, it will be found that in addition to the increased number of cases treated in 1908, the number of recoveries amounting to 1,379 treated within the first twenty-four hours also occurred in children between the ages of five and nine years; that the percentage of deaths has been reduced to 6.56 per cent.; and that the early use of Antitoxin in increased dosage is gradually reducing the death rate among the poor.

In Table No. 4, showing treatment of diphtheria Antitoxin according to areas affected and period of initial treatment after onset of disease, it will be shown that again, as in the previous year, the largest number of cases treated were of the type known as Tonsillar diphtheria; there being 2,611 cases with but 46 deaths, or a death rate of only 1.76 per cent. The highest death rate shown in this table appears where the cases developed all the four types, combined "Post-Nasal, Tonsillar, Pharyngeal and Laryngeal," producing a death rate of 42.85 per cent. in a total of 63 cases with 27 deaths.

In Table No. 5, showing results of treatment of diphtheria with Antitoxin in the several counties by the months for 1908, it will be seen that diphtheria was prevalent in all the sixty-six counties in the State where Antitoxin was distributed for the treatment of diphtheria among the poor, except Fulton and Pike counties; that Luzerne county heads the list with the largest number of cases treated, or 844, with 81 deaths; Lackawanna county comes second with 788 cases treated with 72 deaths, and Allegheny county is third with 563 cases treated with 35 deaths. The lowest death rate is found in Mifflin county, where 147 cases were treated among the poor with but 3 deaths, showing the remarkably low mortality of 2.04 per cent. Another interesting feature shown by this table is that the treatment of diphtheria in Beaver county with 6 cases; Butler county with 13 cases; Cameron county with 1 case; Forest county with 4 cases; Green county with 7 cases; Huntingdon county with 8 cases; Mercer county with 32 cases; Perry county with 10 cases; Potter county with

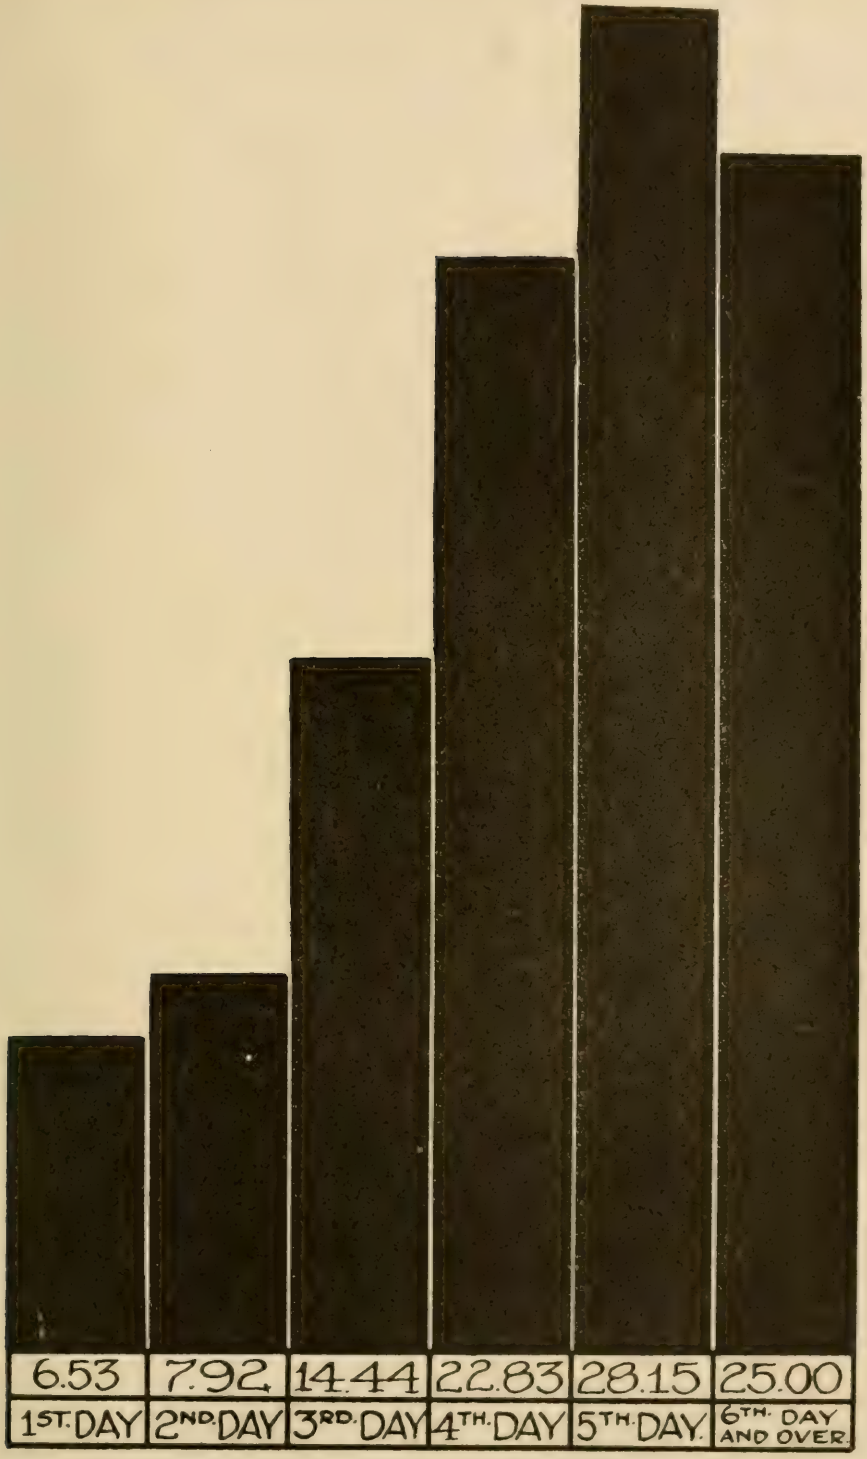

Diagram Showing Percentage of Deaths of Cases Treated With Diphtheria Antitoxin According to Duration of Disease for 1908.

1 case; Snyder county with 14 cases; Union county with 10 cases; Venango county with 7 cases and Wyoming county with 34 cases, resulted in each county in 100 per cent. of recoveries.

Table No. 6, showing result of treatment of diphtheria with Antitoxin according to number of units used and period of treatment after onset, reveals the fact that the initial curative dose, or 3,000 units of Antitoxin, was administered within the first twenty-four hours of onset in 2,019 cases, with only 82 deaths, or a death rate of 4.06 per cent. It also reveals the fact that much more Antitoxin has been used in the entire treatment of any single case, the largest amount of Antitoxin used being 117,000 units to effect the recovery in one case. A careful inspection of this table shows that the number of units used for the entire treatment of any one of the cases will range from 1,000 units by gradual increases until the maximum number of 117,000 is reached. It also shows that double the initial or curative dose of 3,000 units of Antitoxin was used within the first twenty-four hours of onset in 922 cases, with but 60 deaths, or a death rate of 6.50 per cent. A still further examination of this table will show that three times the initial dose, or 9,000 units of Antitoxin, was used within the first twenty-four hours of onset in 264 cases, with only 32 deaths.

Table No. 7, showing the number of cases where subsequent treatments of Antitoxin were administered after the first twenty-four hours, it will be seen that the number of units used in these subsequent treatments range all the way from 1,000 units up to the maximum number of 33,000 units. It will also be seen in this Table that subsequent treatments with only 3,000 units of Antitoxin after the first twenty-four hours were administered in 1,041 cases with 81 deaths, or a mortality of 7.78 per cent. Also that subsequent treatments of *double* the initial curative doses, or *6,000* units of Antitoxin, were administered to 609 persons, with only 84 deaths.

It might be stated just here for the information of the physicians throughout the State of Pennsylvania, that on or about August 26, 1908, 5,000 unit packages of Antitoxin were sent as an experiment to a few distributors for use of physicians living a considerable distance from the nearest distributing station, but not a sufficient number of cases have as yet been treated with this increased dosage to admit of the compilation of statistical data of value at this time. Suffice it to say, however, that the outlook is encouraging from the few clinical reports already received from physicians.

The total number of cases treated has been arranged into one set of Tables, numbered from 1 to 8; No. 1 to 7, inclusive, covering curative treatment, and No. 8, immunization treatment, which give in detail the number of cases treated from January 1, 1908, to December 31, 1908, and show the results as tabulated under the following headings:

1. Period of Initial Treatment After Onset of Disease.
2. Showing Results of Treatment According to Sex and Age.
3. Period of Initial Treatment After Onset and Age.
4. Areas Affected and Period of Initial Treatment After Onset of Disease.
5. Number of Cases Treated in the Several Counties of the State by the Months, with Result.
6. Result of Treatment of Diphtheria with Antitoxin According to Number of Units Used and Period of Treatment After Onset of Disease.
7. Statement Showing Cases Where Subsequent Treatments of Antitoxin were Used After the First Twenty-four Hours.
8. Number Immunized, with Result.

IMMUNIZATION TREATMENT FOR THE YEAR 1908.

In addition to the curative treatment of Diphtheria for which Antitoxin is furnished free by the State to the indigent, the Department of Health also furnishes free for use in preventing the spread of diphtheria what is known as an immunizing dose of Antitoxin, 1,000 units in strength, with which physicians are instructed to immunize all those in the household where the true case of diphtheria is found as well as all those outside of the house who may have come in contact with the patient.

Physicians are also requested and they agree when receipting for the Antitoxin from the Distributor, to furnish the Department with a clinical report for all persons immunized as well as for all those treated for cure, and the clinical reports received in which Antitoxin furnished by the State had been used, for the purpose of the immunization of persons who had been exposed to diphtheria from January 1st to December 31, 1908, show that three thousand nine hundred and sixty-five (3,965) persons had been immunized, of which number but 45 were reported as having contracted the disease at some time within twenty-one days after they had been immunized.

If physicians would follow instructions in regard to immunizing all those in the immediate vicinity of the patient at once, it would go far toward stopping the spread of the disease, if not altogether eliminating the chances of an epidemic.

For results in detail of the treatment for immunization during the year 1908, the following Table is presented:

TABLE VIII.

Showing the Results of Treatment for Immunization, 1908.

Number Treated for Immunization.	Units used.	Number not developing diphtheria.	Number developing diphtheria.	Recoveries.	Deaths.
1,	200	1	0	0	0
1,	300	1	0	0	0
126,	500	126	0	0	0
5,	750	5	0	0	0

5,	6,000	5	0	0	0
1,	7,000	1	0	0	0
1,	10,000	1	0	0	0

The following statement giving the number of syringes of Diphtheria Antitoxin supplied to Distributors during the three months of 1905 and during each month for the years 1906-1907 and 1908 shows a steadily increasing demand for the use of this life-saving agent in the treatment of diphtheria among the poor and also reveals the fact that from October, 1905, to December 31, 1908, there was supplied to Distributors of Antitoxin located in every county in the State, 19,562 packages of 1,000 units, or immunizing doses of Antitoxin; 30,762 packages of 3,000 units and 115 packages of 5,000 units, or curative doses of Antitoxin.

The following statements show the number of packages of 1,000, 3,000 and 5,000 units of Diphtheria Antitoxin supplied, as well as dispensed by Distributors, located throughout the entire State of

Pennsylvania, each month during the year 1908 and also reveals the fact that the demand for and use of Antitoxin for the treatment of diphtheria among the poor is steadily increasing every year.

The following statements by years give a concise summary of the whole number of cases treated; number of deaths; percentage of deaths; number immunized; number immunized and later contracting the disease; the number of syringes, 1,000 units, 3,000 and 5,000 units of Antitoxin supplied to and dispensed by Distributors and total cost for each year; and the General Summary for the years 1905, 1906, 1907 and 1908 giving the totals of each item since the Depart-

ment of Health began distributing Antitoxin for the treatment of diphtheria among the poor, in October, 1905, until December 31, 1908, just three years and three months, reveals the fact that out of a grand total of 15,429 cases treated for cure, but 1,349 resulted fatally, or a death rate of only 8.74 per cent. and in addition to the number treated for cure 10,253 persons mostly little children who were exposed to the disease were immunized and of the above mentioned number of persons so immunized only 161 contracted Diphtheria, and of those who contracted the disease, only thirteen died.

The total cost of Antitoxin used in the treatment of the 15,429 cases for cure and the 10,253 cases that were immunized or a grand total of 25,682 cases treated from October, 1905, to December 31, 1908, was $54,887.65, or about $2.13 per capita.

SUMMARY.

1905.

Number of cases cured during October, November and December, 1905,	255
Number of deaths,	38
Total number treated,	293
Percentage of deaths,	12.98
Number immunized,	155
Number immunized and later contracting the disease,	5
Number of syringes, 1,000 units, dispensed by distributors,	327
Number of syringes, 3,000 units, dispensed by distributors,	619
Total cost (including "Initial Supply") which cost $6,199.73,	$7,251.80

1906.

Number of cases cured from January 1st to December 31, 1906,	3,136
Number of deaths,	393
Total number treated,	3,529
Percentage of deaths,	11.12
Number immunized,	2,334
Number immunized and later contracting the disease, (total),	77
Number immunized and later contracting the disease (recovered),	74
Number immunized and later contracting the disease (deaths),	3
Number of syringes, 1,000 units, dispensed by distributors,	3,725
Number of syringes, 3,000 units, dispensed by distributors,	6,564
Total cost,	$16,192.32

1907.

Number of cases from January 1 to December 31, 1907,	4,985
Number of deaths,	376
Total number treated,	5,271
Percentage of deaths,	7.13
Number immunized,	3,799
Number immunized and later contracting the disease (total),	34

THE DISTRIBUTION OF VACCINE AND VACCINE SUPPLIES.

The free distribution of Vaccine and Vaccine supplies is made by the Department of Health through the Division of Distribution of Biological Products only to second-class townships and only to those people therein who are too poor to purchase the same, where no Boards of Health exist, also to boroughs just organized and to charitable institutions in Pennsylvania not receiving appropriations

from the State, at the request of physicians located in any county in the State—excepting Philadelphia county—upon the recommendation of the County Medical Inspectors.

Under the urgency of a serious epidemic, however, the stringency of this rule may be relaxed; the safety of the people being of vastly more importance than economy in administration.

During the year 1908 smallpox was found in thirty-four different localities throughout the entire State, viz:

Pittsburg, Allegheny Co.; Freedom, Beaver Co.; Sayre, Bradford Co.; Centre township, Keenan, Butler, Eau Claire, Bessemer Coal Mines, Venango township, Butler Co.; Croyl township and South Fork, Cambria Co.; Coatesville, Chester Co.; Meadville, Linesville Boro and Conneaut township, Crawford Co.; Mechanicsburg, Enola, New Kingston, West Fairview, Carlisle, Cumberland Co.; Harrisburg, Halifax, Dauphin Co.; Summit township, Erie Co.; Mt. Union, Huntingdon Co.; McCalmont township, Jefferson Co.; North Annville, Lebanon Co.; New Smithville, Weisenberg township, Lehigh Co.; Gracedale and Mt. Top, Luzerne Co.; Lower Merion, Montgomery Co.; Philadelphia, Philadelphia Co.; Glade township and Sheffield, Warren Co.

Only 770 Glycerinized Vaccine Points and 390 tubes of Vaccine Lymph for use in the vaccination of persons exposed to smallpox were supplied upon requisition through the proper channels in twelve different localities, the entire cost for furnishing same being only $45.23.

The following statement shows the number of cases of Smallpox occurring throughout the State of Pennsylvania during the year 1906, 1907 and 1908, by the months.

SANATORIA AND DISPENSARIES FOR THE TREATMENT OF TUBERCULOSIS.

South Mountain Sanatorium: FREDERICK C. JOHNSON, M. D., *Medical Director.*

Dispensaries: THOMAS H. A. STITES, M. D., *Medical Inspector of Dispensaries.*

PENNSYLVANIA STATE SOUTH MOUNTAIN SANATORIUM FOR TUBERCULOSIS.

Report for the Year Ending May 31, 1909.

MEDICAL AND NURSING STAFF AND EMPLOYES.

Dr. Fred C. Johnson, Medical Director, McKean County.
Dr. B. S. Putts, Associate Medical Director, Allegheny County.

PHYSICIANS.

Dr. A. M. Rothrock, Chester County.
Dr. J. W. MacMullen, Dauphin County.
Dr. J. Edward Nickel, Dauphin County.
Dr. H. H. Thomsen, Philadelphia County.
Dr. F. C. Hyatt, Philadelphia County.
Dr. H. P. Lynch, Dauphin County.
Dr. J. P. Marshall, Berks County.
Dr. H. C. Lacy, Berks County.
Dr. W. G. Marks, Philadelphia County.
Dr. Benjamin F. Robinson, Philadelphia County.
Dr. Carl Koenig, Allegheny County.
Dr. George H. Fox, Bacteriologist, Dauphin County.

STENOGRAPHERS.

Martha O. Adams, Dauphin County.
Caroline B. Haifleigh, Dauphin County.
L. Walter Garrett, Clerk, Chester County.

MATRONS.

Miss Maud Emery, Clinton County.
Mrs. Annie M. Klee, Franklin County.
Mrs. Annie Yeager, Assistant Matron, Franklin County.

NURSES.

Addah Strouse, Head Nurse, Philadelphia County.
Myra E. Preble, Franklin County.
Catherine Cadden, Luzerne County.
Selina Wilder, Philadelphia County.
Mary E. Lyons, Philadelphia County.
Rachiel Ross, Philadelphia County.
Mary Clark, Sullivan County.
Gertrude Snyder, Northampton County.
Edith Keister, Dauphin County.
Mathielde Bayer, Philadelphia County.
Mary Ekhart, Philadelphia County.
Florence Laskowski, Philadelphia County.
Elenore O. Risso, Philadelphia County.
Agnes Martin, Lackawanna County.
Lottie Reynolds, Franklin County.
Elizabeth McMahon, Lycoming County.
Alice McKernen, Philadelphia County.
Sarah Zimmerman, Philadelphia County.
A. Irene Ramage, Philadelphia County.
Helen Gimmell, Philadelphia County.
Tusanna Walker, Northampton County.
Emma Ibbetson, Philadelphia County.
Alice Pilkington, Philadelphia County.
Carrie Epley, Cumberland County.
Myrtle Cook, Dauphin County.
Eleanore Lehman, Dauphin County.
14 Orderlies.
7 Ward Maids.

DINING ROOM.

Catherine Strine, Cook, Dauphin County.
Mrs. Mary Souder, Assistant Cook, Dauphin County.
3 Waitresses.
3 Chambermaids.

SEAMSTRESSES.

Julia Boyle, Dauphin County.
Josie Garber, Lancaster County.

MAIN DINING ROOM BUILDING.

Charley Hutz, Chef, Franklin County.
Elizabeth Rosenberger, Assistant Chef, Franklin County.
36 Waitresses.
14 Maids and Helpers.

MISCELLANEOUS.

Wilson Reynolds, Superintendent, Franklin County.
Louis Sorg, Steward, Philadelphia County.
J. T. Staley, General Foreman, Franklin County.
George Naugle, General Foreman, Franklin County.
C. R. Forbes, Resident Engineer, Lancaster County.
George C. Metzgar, Storekeeper, Philadelphia County.
George Thompson, Assistant Storekeeper, Philadelphia County.
Arthur Yeager, Master Mechanic, Franklin County.
J. N. Reed, Foreman over Foreigners, Franklin County.
Nelson Anderson, Special Officer, Lancaster County.
Leo Pavlick, Special Officer, Philadelphia County.
Clarence W. Durr, Night Watchman, York County.
J. Wesley Dix, Night Watchman, Philadelphia County.
Charles H. Hill, Fireman-Carpenter, Dauphin County.
George A. Staley, Fireman, Adams County.
James Daywalt, Fireman, Adams County.
Samuel Staley, Fireman, Franklin County.
Maurice Lightner, Fireman, Adams County.
Ben Carbaugh, Caretaker of Filter Plant, Franklin County.
Daniel Staley, Pump Runner, Franklin County.
Harry Baker, Traction Engine Runner, Franklin County.
H. S. Hay, Laundryman, Northampton County.
Levi Wagaman, Poultryman, Franklin County.
Charles Marceline, Chef, Philadelphia County.

INFIRMARY.

William Beitzel, Chef, Philadelphia County.
Daniel Fegler, Assistant Chef, Berks County.
3 Kitchen Helpers.
7 Waitresses.
1 Chambermaid.

REPORT.

At the beginning of the year, June 1, 1908, there were one hundred and thirty-three (133) patients under treatment, of whom eighty (80) were males and fifty-three (53) females.

During the year, seven hundred and twenty (720) males and three hundred and sixty-nine (369) females, a total of one thousand and eighty-nine (1,089) patients were treated, while five hundred and

eighty-nine (589) were discharged, four hundred and seven (407) males and one hundred and eighty-two (182) females, of whom thirty-four (34) died, twenty-six (26) males and eight (8) females.

On June 1, 1909, there were remaining in the Sanatorium five hundred (500) patients, of whom three hundred and thirteen (313) were males and one hundred and eighty-seven (187) females. Of these, three hundred and fifty-six (356) were under treatment in the Incipient Camp and one hundred and forty-four (144) in the Infirmary Wards.

There were one thousand seven hundred and forty-nine (1,749) applications for admission, of whom nine hundred and fifty-six (956) were admitted, one hundred and seventy-five (175) refused to come, four hundred and ninety-two (492) failed to reply to admission notices, forty-one (41) had died, and twenty-five (25) were too ill to travel. Sixty (60) were children under fourteen years of age, whose moral, mental and physical welfare demands more care and surveillance than is possible to give them under the cottage plan of treatment. The completion of the Children's Hospital will, therefore, greatly enhance the usefulness of the Institution.

Over 38 per cent. of cases treated were from Philadelphia and Allegheny Counties.

The exactions with regard to admission have insured a majority of native born patients (78.14 per cent.).

Of the balance, 6.61 per cent. were from Russia; 2.75 per cent. were from Ireland; 2.02 per cent. were from Germany; 1.95 per cent. were from England; 1.74 per cent. were from Italy; 1.65 per cent. were from Austria.

Our statistics bear out the statement that Tuberculosis is a disease of early adult life, as 66.39 per cent. of patients treated during the year were not over thirty years of age. Of these, 62.51 per cent. were males.

The occupations of applicants have been varied, but evidence the fact that Tuberculosis claims more victims among those following indoor occupations.

The completion and equipment of the Infirmary Building early in February added one hundred and forty-four (144) cases to our constantly increasing population. Cases admitted to these wards have not all proven hopeless, as many with the disease active have later improved sufficiently under rest in bed and proper diet to be transferred to the Incipient Camp. Prior to the opening of the Infirmary Wards, cases wearied by a tedious journey were of necessity segregated in cottages near the dining-room and cared for under great disadvantages. At present, all cases are given a preliminary examination at the Infirmary, and, if necessary, retained there until physically able to take up the life and environment of the Incipient Camp.

Of the incipient cases discharged, sixty-seven (67) in number, thirty-four (34) were arrested, twenty-eight (28) improved and five (5) left unimproved.

Our patients generally are unwilling to remain in the Institution after active signs of the disease have disappeared. The majority of them are wage-earners and of necessity compelled to leave the Sanatorium and resume employment as soon as they have regained sufficient strength to do so. It seems a justifiable assertion, therefore, that the majority of these cases, were they able to continue treatment at the Sanatorium, could be discharged as arrested cases and subsequently go on to cure under favorable conditions.

This, in part, is true of the moderately advanced class discharged, two hundred and fifty-two (252) cases, of whom fifty-nine (59) were arrested, one hundred and thirty-nine (139) improved and fifty (50) unimproved, while four (4) died.

Of the far advanced class discharged, two hundred and seventy (270) cases, thirty-two (32) were arrested, and one hundred and fourteen (114) improved, ninety-four (94) unimproved and thirty (30) died.

Of the incipient class discharged, sixty-seven (67) cases, sixty-two (62) gained in weight, two (2) remained stationary and three (3) lost weight.

Of the moderately advanced class discharged, two hundred and fifty-two (252) cases, two hundred and six (206) gained in weight, thirteen (13) remained stationery and thirty-three (33) lost weight.

Of the far advanced class discharged, two hundred and seventy (270) cases, one hundred and sixty-four (164) gained in weight, twenty-two (22) remained stationary and eighty-four (84) lost weight.

The provision of quarters for the treatment of patients with Tuberculin permits of the selection of proper cases, which has not obtained heretofore, its use being limited to those who requested such treatment, and, unfortunately, of this class the disease has made such progress that entirely satisfactory results could hardly be expected. Of the favorable cases, however, the results have been such that our belief in the permanent immunization of tuberculosis subjects with Tuberculin is strongly confirmed. The benefit that will accrue to that class of patients who so frequently suffer from relapses, following the cessation of Sanatorium treatment, is incalculable. This treatment frequently begun at the State Dispensaries is continued following admission of the patient to the Sanatorium and in turn carried on at the Dispensaries after discharge of the patient from the Institution.

Thus far our work has been confined to the use of Emulsion of Dead Tubercle Bacilli (B. E.) and the Water Extract, prepared after the method of Dixon (Medical News, October 19, 1889). With the con-

tinuance of this work and with the results anticipated among selected cases, we feel sure of being able to make material additions to the literature subsequently.

Besides the specific treatment we have endeavored to keep firmly in mind the objects for which our State has provided this Institution, viz:

First: "Benefit to the individual" whereby he not only regains health but again becomes a support to his family.

Second: Increase of the resources of the Commonwealth.

Third: "Segregation," which removes him as a source of infection while he is returning to health, and in addition provides for the proper care and treatment of incurable cases who are often excluded from other Institutions, and become centers of infection.

Fourth: "Educational Features," which do not stop with instructing the patient how to live and protect others from infection, but often start an endless chain by their exemplary habits.

The basis of treatment may be summarized as nourishing food, rest, fresh air and sunlight.

Medicinal agents are used only for the relief of co-incident symptoms and conditions as they appear.

Impaired digestion is undoubtedly the cause of a great number of failures, for in no other branch of medicine is this vicious sequel of nostrums and quackery more apparent than among sufferers from Pulmonary Tuberculosis.

Exercise and light work, carefully graduated, form a part of the treatment of convalescent patients, both being increased as the condition of the patient permits.

The "Daily Routine" observed by our patients is as follows:

DAILY ROUTINE.

6:30 A. M.	Rising Hour.
7:15 A. M.	Breakfast.
7:30 to 9:30 A. M.	Temperatures and cleaning quarters.
9:30 A. M.	Lunch.
10 to 11:30 A. M.	Rest in pavilions (or exercise)
12:00 M	Dinner.
1:00 to 2:30 P. M.	Rest in reclining position on bed.
2:30 P. M.	Lunch.
3:00 to 4.30 P. M.	Rest in pavilions (or exercise).
5:00 P. M.	Supper.
5:30 P. M.	Distribution of mail.
5:45 P. M.	Temperatures.
7:30 P. M.	Lunch.
8:30 P. M.	Retiring Hour.
9:00 P. M.	Lights out

The completion of the Laboratory Building with its added equipment affords opportunity for more extensive and systematic work than has been possible heretofore.

Our aim has been a monthly examination of sputum, following the examination of both the urine and sputum of all patients on admission.

Examination of the sputum each month of the cases treated has been made with a view to eliminating unfavorable cases of mixed infection.

The record of sputum examinations is as follows:

	Total.	Tubercle bacilli present.	Not found.
June,	381	263	118
July,	412	337	75
August,	346	283	63
September,	159	117	42
October,	394	272	122
November,	157	94	63
December,	244	150	94
January,	139	103	36
February,	142	81	61
March,	372	191	181
April,	279	181	98
May,	100	52	48
Grand total,	3,125	2,124	1,001

Re-examination of the sputum of arrested cases has largely contributed to the results of examinations in which tubercle bacilli were not found.

A study has been made of the sputum with regard to its phagocytic content. While the work has proven interesting, no noteworthy deductions have been elicited.

During the year nineteen hundred and seventy-two (1,972) urine examinations were made and detailed reports filed with the patient's records.

The difficulty of obtaining permission for autopsies has handicapped the verification of clinical symptoms by accurate pathological findings at post mortem. However, special efforts have been made to work up exceptional cases, of which the following was most interesting from the diagnostic point of view:

L. M., a typical, far advanced case, thirty-two (32) years of age, was admitted on November 20, 1908. Duration of the disease probably ten (10) years, although active symptoms began only in the last two (2) years. Upon admission, weighed one hundred and thirty-two

and one-half pounds and general condition fairly good. Physical examination was negative except that the lungs showed marked softening at the right upper and lower lobes and left apex, with signs of cavity at right upper lobe.

During his stay of sixty-two (62) days there was a slight gain in weight without active febrile symptoms. He was making fairly satisfactory progress until about four weeks prior to his death when he suffered from a rather sharp attack of Herpes Zoster. This attack subsided slowly but the patient then began to exhibit further symptoms of spinal disturbance, suggesting incipient tabes, such as girdle pains, poor station, exaggerated knee jerks, with sluggish pupillary reactions. Combined with these symptoms was a slight but definite transitory cerebral excitement. About one week prior to death he became mentally dull and apathetic, followed by a mild wandering delirium with slow pulse and sub-normal temperature until his death on January 21, 1909. An autopsy verified the thoracic clinical signs, while the following report made by Dr. Allen J. Smith, Director of the Department of Health Laboratories, cleared up the symptoms referable to the spinal cord:

"Sections of cord taken from dorsal region show the existence of a marked meningo-myelitis, characterized by a marked diffuse infiltration of the surface of the cord, of the perineural sheaths and the membranes by lymphocytes, and attended by oedema and a minor fibrin deposit in the distended lymph spaces. Endothelial proliferation of many of the blood vessels, almost or quite to obliteration, perivascular collection of lymphocytes, and endothelial formations, and injection of the vessels prevails. In a few isolated miliary foci caseation exists; no definite giant cells noted. The vascular thickening is not of the fibrous type commonly expected of a luetic process, is rather cellular in type from proliferation of the lining endothelium and of the endothelial cells of the perivascular lymph spaces. Special staining shows the presence of tubercle bacilli in small numbers.

From the above points the diagnosis of a tuberculous meningo-myelitis is evident. A lymphocytic collection of small grade exists in the commisure about the central canal; and along many of the small vessels of the cord a slight collection of the same type is to be seen. Alteration of the staining quality, discoloration of the nucleus and loss of shape of multipolar cells is noted occasionally. Most of the cells are apparently normal. The process probably extended along the sheaths of the spinal nerves for some distance from the cord, judging from the grade of changes present in the portions attached. Diagnosis: Tuberculous meningo-myelitis."

The responsibility of preserving the purity of a food product so easily contaminated as milk, in the quantity required, is obviously considerable. Despite frequent examinations of milk and inspections

of the dairy farms from which our supply of milk is derived, four (4) cases of Enteric fever occurred during the month of November. The cases were directly traceable to milk supplied from a dairy farm upon which three (3) ambulant cases of Enteric fever were discovered by members of the Department.

A farm hand first showed symptoms of the disease and was sent to a nearby hospital, where he made a satisfactory recovery. After an incubation period of about sixteen days both the farmer and his wife contracted a very mild but unmistakable type of the disease.

The physician attending the cases was arrested and fined for his neglect to report these cases to the Department of Health.

Of the cases stricken with the disease at the Sanatorium, all were males, quartered in a group of cottages, containing one hundred and sixty (160) patients, of whom four (4) were regarded as suspects, but none of these responded to the Widal test, and recovered promptly without developing any pathognomonic signs of the disease. All of the demonstratable cases were of the same cycle of infection, and it appears probable that the duration of exposure was brief, possibly but one milk delivery acting as the vehicle of infection. All of the patients made uneventful recoveries without the development of any secondary cases.

Of three (3) moderately advanced cases the course of the disease did not appear to be materially influenced by the added infection, while in one far advanced case the patient failed progressively afterward with evidence of increased activity of the disease until his discharge on January 4, 1909.

No other cases of communicable disease occurred in the Institution during the year except one case of Varicella and one of Measles. Both were properly isolated and no further extension of the disease resulted.

On the discharge of patients from the Sanatorium the Dispensaries through which they applied for admission are notified. This permits of continued surveillance over them by the Local Dispensary Authorities and thus reduces to a minimum the relapses that have been only too common among discharged Sanatorium cases heretofore.

Cases traveling to and from the Sanatorium are provided with individual drinking cups and the accessories for the care of sputum, thus preventing many opportunities of infection to the traveling public. Outgoing mail, as well as the effects of discharged and deceased patients, are properly disinfected with formaldhyde gas before leaving the Institution.

Amateur theatricals and the weekly assemblage of patients for games and social intercourse have added much to the contentment of the patients. A large phonograph with many excellent records has also furnished them many enjoyable hours.

A monthly publication, bearing the very appropriate name of "Spunk" has been founded by the patients. It has received many flattering press notices and as a monthly message of good cheer to the afflicted serves to encourage and spur on the struggling patient in his search for health.

Through the generosity of Mrs. Samuel G. Dixon a chapel will be erected on the grounds in memory of her father, John Gilbert. The site has been selected and the architect's plans are nearing completion.

The building will be so arranged that it may be used for worship by all denominations.

Through donations received from time to time the nucleus of a library has been established.

Through the Waynesboro, Shippensburg and Lansdowne Branches of the Needlework Guild of America many deserving patients were furnished with wearing apparel.

Several boxes of clothing have also been received from Mrs. Samuel G. Dixon.

Children's shoes and overshoes were received from the Jerauld Shoe Company of Harrisburg; also a box containing clothing from Messrs. Schwartz Brothers, Johnstown.

I am indebted to and wish to make grateful acknowledgment for the co-operation of the Medical and Nursing Staff, whose arduous and untiring efforts have been with a singleness of purpose that has meant much to the success of the Institution.

During the year the following improvements have been made:

Dining room building, seating five hundred and seventy-six (576) patients. The building affords ample storage facilities in the basement and provides quarters for the help on the second floor.

A modern steam laundry, equipped with washer steam sterilizers and other devices of recent construction.

Infirmary Building and Laboratory, as noted elsewhere.

Acetylene plants have been provided for the lighting of the Infirmary and main dining room buildings.

A concrete mortuary with cold storage facilities for the care of the dead and provisions for post mortem examinations.

Three bath houses, each equipped with showers and provided with a room in which the patient may rest after bathing before going into the open air.

Comfortable, well appointed twin houses of colonial design, have been provided for the Medical Director and the officials.

All the buildings on the grounds, together with the Infirmary Building, have been fitted with fly screens.

An ice pond, covering an area of about 25,000 square feet, together with an icehouse, with a storage capacity sufficient for the needs of the Institution for over two years.

Over two miles of pipe have been laid, connecting our springs to a collecting reservoir with a capacity of 45,000 gallons. Engines and pumps have been installed for use in pumping the water from the collecting reservoir into the storage reservoir, which has a capacity of 300,000 gallons.

At the disposal plant two sand filters, each 40 x 100 feet, and an incinerating plant, consuming 1,500 pounds of garbage daily, have been provided.

Over 1,800 feet of 6-inch sewage pipe have been laid in making sewerage connections to the Infirmary, dining room building, twin houses, bath houses and toilets.

Buildings and screened run-ways for five hundred (500) chickens have been erected.

The alterations on the stable have provided more stalls and a spacious wagon shed, together with suitable quarters for the stable man.

A concrete manure pit has been erected at the stable.

The superstructure is screened from flies and the pit constructed to permit of the draining and collecting of fluid contents for use as a fertilizer on lawns.

At the laundry steam and water jets have been provided for cleansing garbage cans.

A road has been built from the township road to the Infirmary, a distance of 2,450 feet. The road is constructed of crushed stone, and although built in the early months of the year, when weather conditions were most unfavorable, the work has proven most satisfactory and doubtless far better than any road in this vicinity.

Over 4,200 feet of roads and 4,000 feet of walks have been built of crushed stone throughout the Institution enclosures.

The grounds have been almost entirely enclosed with a substantial ribbon wire fence and the posts whitewashed by convalescent patients.

A great deal of work has also been done by the patients in the lower camp that has added very much to its appearance.

The following work is contemplated during the ensuing year:

An additional unit to the incinerating plant, and additional septic tanks at the disposal plant.

A road from the Infirmary to the Incipient Camp via the ice pond; a road from the ice dam to the sewage disposal plant.

Sixty-four (64) cottages for patients.

Nine (9) toilet buildings.

One (1) bath house.

Eight (8) pavilions.

One (1) Dispensary Building.

A Children's Hospital.

Staff dining room and nurses' home.

Addition to patients' dining room.

Addition to laboratory building.

Addition to blacksmith shop.

Additional buildings and run-ways for 500 chickens.

A carpenter shop.

Seeding grounds about the cottages, the planting of shrubbery and hedges throughout the grounds.

Planting and fencing about sixty (60) acres of land on the Monaghan field for farm purposes.

TABLE I.

ADMISSIONS AND DISCHARGES.

	Total.	Male.	Female.
Number of patients in Sanatorium June 1, 1908,	133	80	53

TUBERCULOSIS DISPENSARIES.

Dr. Thos. H. A. Stites, Medical Inspector of Dispensaries.

OFFICE STAFF.

Miss Olive E. Jamison, Stenographer.
Miss Mary Sandoe, Stenographer.
Miss Nellie Tittle, Stenographer.
Miss Josephine Hill, Stenographer.
Miss Mary Fitzpatrick, Clerk.

DISPENSARY MEDICAL STAFF.

In each dispensary there is a Physician-in-Charge appointed at the head of the work. Where the work is great enough to warrant the same, the Commissioner of Health appoints a first assistant physician and a second assistant physician, thus making the medical staff consist of the Physician-in-Charge, one first assistant and one second assistant physician. Subsequent to August 6, 1908, the Commissioner of Health decided upon the remuneration of the first and second assistant physicians as well as the Physician-in-Charge for their services.

VISITING NURSES.

As soon as possible after application for treatment and examination at the dispensary, each patient is visited in the home by a nurse from the dispensary.

The visiting nurse is expected to investigate the conditions in and and around the patient's home, the habits of the family, and the health of the family, while the financial circumstances are also considered important.

Immediately subsequent to the first visit of the nurse a written report on the conditions found is rendered by her to the physician-in-charge. In addition to investigating the surroundings and circumstances of the patient, it is the duty of the nurse to follow up the advice and instructions already given at the dispensary by pointing out the particular manner in which the advice is to be applied. She is expected, so far as possible, to assist in improving conditions about the patient. No effort is spared towards re-arranging the rooms and furniture in such a way as to materially improve the surroundings.

In many ways the work of the visiting nurse is of prime importance, since by coming into the patient's home she becomes far more intimately acquainted, not only with the patient, but with the whole family, than is the case with one who sees the patient only at the dispensary.

The observations and reports of our visiting nurses are of great assistance in preventing misapplication of the supplies furnished by the Department.

OFFICE WORK.

Administrative Work.

The administrative work of the division consists in superintending the distribution of supplies, reviewing reports and vouchers, and personal inspection of the various dispensaries. The Medical Inspector of Dispensaries makes frequent visits to each dispensary, his coming never being known to those in charge of the particular dispensary until his arrival. In this way the Department seeks to assure itself of the maintenace of the dispensaries in proper physical condition, and that the physicians are doing their work as required by the Department.

LOCATION OF DISPENSARIES.

The original plan of distribution of dispensaries was to open one dispensary in each County, This program was completed on June 2, 1908, with the opening of the dispensary at Greensburg, Westmoreland County. Frequent requests and petitions, however, were received by the Commissioner of Health asking him to open other dispensaries. After a careful review of the work of the dispensaries already in operation and of their geographical relations to the various districts of the State, it was decided that the Department should proceed in the extension of the existing system. This extension was begun in October, 1908, and up to December, 18th, thirty-seven (37) additional dispensaries had been opened for the reception of patients. These dispensaries are numbered from 68 to 104. Their locations and names of Physician-in-Charge are shown in the accompanying lists. A further extension of the system is under consideration.

It has been the effort of the Department to place dispensaries at points where they will best serve the needs of the greatest number of people, and to this end careful consideration has been given to lines of communication and centers of population.

SKETCH OF A SCHEME OF TREATMENT.

Circular Addressed to Dispensary Physician.

1. Patient received, personal history, social history, etc., weight, height, pulse, respiration and temperature taken and recorded by assistant or nurse.

2. Careful physical examination by physician in charge of clinic.

3. Obtaining specimens of sputum, forwarding same to State Laboratory; containers supplied by Department.

4. Advice and prescription.

The intention of the Department is to give as little medicine as possible. Principal reliance must be placed upon fresh air, diet, and careful regulation of habits of life of the patient.

An exceedingly important feature of the work of the dispensary is the education of patients and their friends; the forcing upon them of a realization of the contagious nature of the disease and the duty incumbent upon each to do everything necessary to protect themselves and others.

A. Medicines, as little as possible; left to judgment of attending physician in each case.

B. Fresh air and rest. Require each patient to be as much in the open air as possible. Inquire into habit of sleeping; urge open windows; where possible, the swinging of a hammock out of doors; a bed on the porch; a cot in a tent. In daytime as many hours as possible out of doors. Where it can be done this time should be spent in a semirecumbent position and at rest; a steamer chair or hammock with a supply of blankets is an ideal equipment. The hammock is probably the cheaper and is as easily arranged as anything. It will require considerable urging and no little persistence on the part of physicians and nurses to prevail upon patients to take anything like as much fresh air as experience shows to be desirable. Stress must be laid upon the fact that if proper amount of body covering is provided there is no danger of "*catching cold.*" Too many people think that strenuous exercise is desirable; this is a fallacy to be earnestly combatted.

C. Diet. To a certain extent this must be regulated by the digestion of the individual. As a general rule the diet should be liberal and as nourishing as possible. Milk and eggs are important factors. Milk should be taken slowly and often, with a small amount of lime water added in order to prevent gastric disturbances. Eggs should be fresh and are best taken *raw*. Few patients will do this without urging, but seldom is there an instance where it is impossible. Few patients will consume sufficient milk and eggs without continual urging; and it will be found necessary to question each one closely upon each visit to the dispensary. Probably it will be found wisest to have patients take the milk and eggs at regular hours *between meals*.

In this way the amount of food will be most likely to be increased.

D. Habits of life, etc. These should invariably be investigated, and where irregular or erroneous, their correction urged. This must be repeated at frequent intervals. Among the most important features will be found:

1. As much rest and sleep as possible, not only at night but by day.
2. Avoidance of over-exertion at any time.

3. Avoidance of any exertion during presence of fever or exhaustion.

4. Regulation so far as possible of the exercise of the sexual functions. The attending physician is urged to investigate the habits of the unmarried as well as the married, as frequently there will be discovered the existence of habits which are reprehensible, physically as well as morally. The sexual instinct is proverbially excessive among consumptives. This is a delicate subject to handle and must be approached with tact. Experience shows that when properly approached no resentment will be excited.

5. Meals should be taken at regular hours.

6. The bowels should be kept regular.

7. The skin should be kept clean and its function active. Bathing should be regulated and friction with a coarse towel will be found valuable.

8. Clothing. Usually consumptives are too warmly clad; heavy flannel underwear supplemented by thick chest pads is a frequent occurrence in even warm weather. The evil effects of this continual over-clothing are so apparent that great care must be taken to give proper advice in every case. Probably few habits are so universal among consumptives as is this of over-clothing. Clothing should conform to the weather; too much or too little is equally bad. Patients must be warned to avoid *wet* feet.

9. Use of stimulants or narcotics. This should be particularly noted and cut to the lowest possible point. The dispensary cannot afford to waste effort and help upon those who decline to help themselves. Except in extreme cases stimulants are of little or no value, the effects in the long run being bad rather than good.

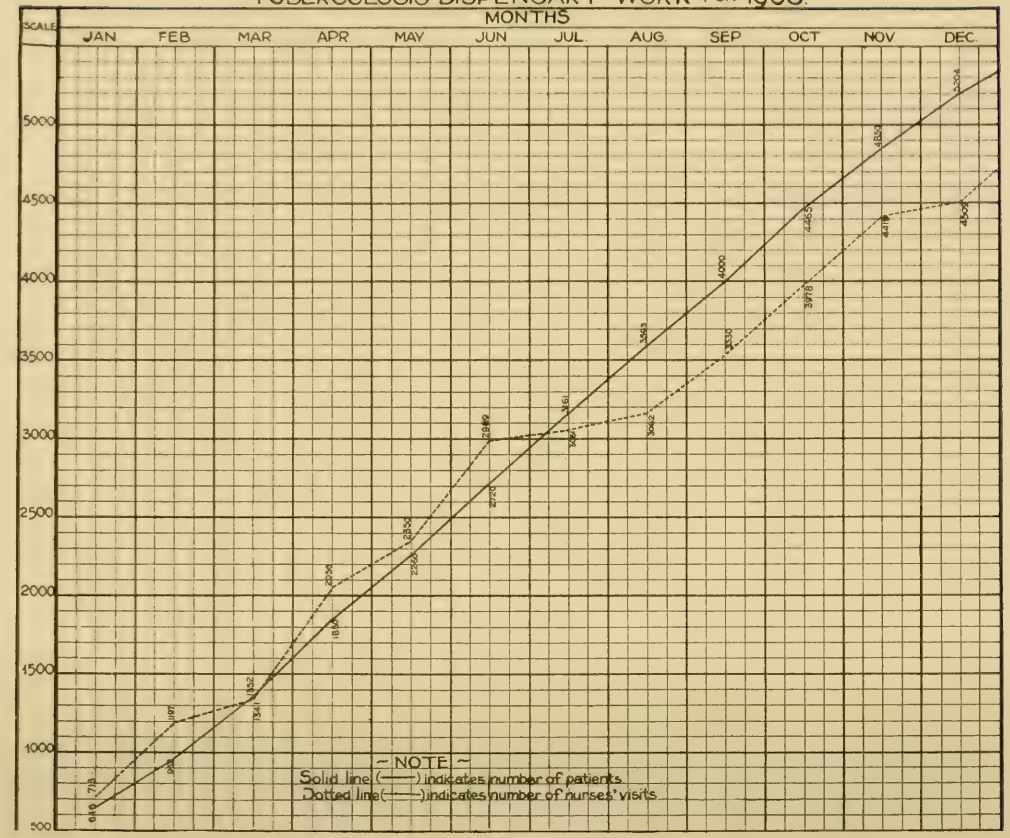
E. Education. Each person must be told that his or her disease is communicable, and that only care on his or her part will stand between those 'round about and the acquiring of the disease.

Close personal contact is dangerous; use of common towels must be avoided; a separate bedroom should be strongly urged, and under no circumstances should a consumptive be allowed to occupy the same bed with any other person. Instruction must be given as to the proper care and disinfection of clothing, bedding, eating utensils and all articles used by the patient. The proper disposal of *sputum* must be carefully explained; burning being the only sure road to safety. Kissing is a habit which is hard to regulate, but we do not do our duty if we fail to warn against it.

Members of the family are very much exposed to infection and any cough or loss of weight must receive attention. The dispensary is open for the examination of all such. In other words, the dispensary is founded as much with the idea of protection to the uninfected as for the curing of the infected.

CHART SHOWING

TUBERCULOSIS DISPENSARY WORK FOR 1908.



The statistical report on dispensary patients appended hereto, includes all patients examined from July 22, 1907, the date of opening of the first dispensary, up to and including December 31, 1908. Seventeen (17) dispensaries were opened during the year 1907. Fifty (50) dispensaries were opened between January 1, 1908, and June 1, 1908. Thirty-seven (37) dispensaries were opened between June 1, 1908, and December 31, 1908.

A few points of interest to which attention may be specially directed are as follows:

Of all applicants examined 71.8 per cent were found tuberculous.
50.2 per cent. patients were males.
49.8 per cent. patients were females.
48.8 per cent. patients married.
95.11 per cent. patients white race.
81.2 per cent. patients native born.
30.8 years average age of patients.

Of the 6,728 tuberculous patients, no less than 1,891 were women engaged in household duties; 701 were laborers, not including those engaged in agricultural pursuits; 199 were bookkeepers and clerks; 139 were textile mill and factory operatives; 299 were miners and quarrymen; 106 were farmers and farm laborers; 97.1 per cent. suffered from tuberculosis of the lungs. The average length of time under treatment was 4.87 months. 48.5 per cent. of the tuberculous patients reported that they had at some time been in direct contact with other tuberculous sufferers. The average family income per month was found to be $24.63. The average family was found to consist of 4.38 members, making the average per capita family income $5.60 per month.

Concerning the seat of the tuberculous lesions of the lungs, the following are the facts found:

The upper right lobe was the most frequent and was found in 5,095 patients. The upper left lobe was found involved in 3,498 cases. The middle right lobe was affected in 1,020 cases. More than one lobe was found involved in 4,756 and in 1,972 but one lobe was involved.

STATISTICAL REPORT ON DISPENSARY PATIENTS.

Form 108.

COMMONWEALTH OF PENNSYLVANIA.
DEPARTMENT OF HEALTH.

Rules to be observed by patients, nurses and attendants in the management of
PULMONARY TUBERCULOSIS (CONSUMPTION).

Never forget that Pulmonary Tuberculosis (Consumption) is an infectious disease and can be prevented.

All sputum must be collected and thoroughly disinfected, preferably by burning. If you are careless in this regard, you may reinfect yourself and will become a menace to others who may inhale the dust resulting from the dried sputum.

Do not spit on the floor or the sidewalk.

A pressed paper spit cup, or a paper cup held in a metal frame, should be used, and these cups must be burned after using.

If a china or earthen spit cup is used, keep lye or water in it all the time and scald it out once or twice daily.

Never spit in rags or handkerchiefs. Always carry with you a supply of paper napkins on which to wipe your mouth, or in which to spit in case of emergency. Carry a paper bag in which to place the soiled napkins and burn the bag, with its contents, at the end of the day.

Never swallow your sputum.

You should occupy a well-ventilated, sunny room, from which all unnecessary furniture, such as carpets and hangings, has been removed.

Always sleep with the windows open, but have them well screened so as to prevent the entrance of insects.

Sleep in a room by yourself, if possible. If not, have a separate bed.

Keep clean shaven, especially about the mouth, as the beard is usually infected and may be responsible for your reinfection.

Avoid getting sputum on the bed or body clothing, carpets or furniture, or in fact in any place where it may become dry. The outer covering on your bed should be of material that can be frequently washed and boiled.

Have your own individual towels, handkerchiefs and toilet articles.

Handle the soiled bed and body linen, particularly handkerchiefs, as little as possible. Place such articles in water containing Chlorinated Lime, in the proportion of one quarter pound to eight gallons of water, until ready to be washed.

Never use a broom or dry duster in your room. Cleansing, except for metal fixtures, should be done with a cloth moistened in a solution made by dissolving eight Bichloride of Mercury tablets in every gallon of water used.

Since Bichloride of Mercury is very poisonous when taken internally, bottles containing it should be plainly labeled "Poison," and placed beyond the reach of children.

Never kiss anyone upon the mouth. It would be better to avoid this practice entirely as well as handshaking.

Always wash your hands thoroughly and clean your finger nails before eating.

Remember that rest, fresh air, sunlight, and good food, are essential to your improvement.

Take medicine only upon the advice of a physician. Good digestion is one of the greatest implements in the fight against tuberculosis. It is often destroyed by the use of patent medicines which frequently rob the patient of his last chance of recovery.

Live in the open air during winter and summer as much as possible. Avoid dust and smoke.

Those suffering from tuberculosis should not follow any occupation which requires the handling of food stuffs.

Dress consistently with the season. Avoid chest protectors and tight clothing, particularly corsets. Keep your feet dry and warm at all times.

Take exercise only upon the advice of a physician and then never to the extent of fatigue.

Go to bed early so as to get rest and if possible sleep at least eight hours.

Keep your body clean, take a warm bath at least once a week and be sure to rinse the body thoroughly of soap used in bathing. Never take cold douches or cold baths except by direction of a physician.

Do not eat when physically or mentally tired, or when excited. All meals should be preceded and followed by a period of rest in bed, or in a reclining chair.

Rinse your mouth before meals.

Eat plenty of good wholesome food at meal time, supplementing this with milk and eggs as directed by a physician.

Eat slowly, chew your food well and avoid anything which causes indigestion.

Sweet meats and pastry are especially to be avoided.

The teeth and mouth should be kept in good condition, by the use of a tooth brush, especially at bed time and upon rising in the morning. Always disinfect your toothbrush after using and never keep it where it will come in contact with a brush used by any one else.

The use of wines, liquors and tobacco, is prohibited except by order of a physician.

See that your bowels move regularly every day.

Whenever you have a temperature which is 99.5 degrees, diarrhoea or reddish expectoration, you should remain in bed.

If you should have a hemorrhage, keep as quiet as possible and send for a physician.

At all times endeavor to control your cough as much as possible, but when you are obliged to cough cover your mouth with a paper napkin.

Under all circumstances obey the instructions of your physician minutely, and if there is any doubt in your mind as to what you ought to do, consult him.

In order to prevent others contracting the disease, your room should be disinfected before being used by another person. You are therefore requested to send word to the Township Health Officer upon removal, in order that the work of disinfection may be done by the department.

Sputum cups, paper napkins and bags, are supplied to patients attending State Dispensaries.

If attending the Dispensary, regular visits will be required until discharged by the physician in charge.

SAMUEL G. DIXON, M. D.

DESCRIPTIVE CATALOGUE

THE EXHIBIT OF THE

STATE DEPARTMENT OF HEALTH

Of Pennsylvania

AT THE

International Congress on Tuberculosis

WASHINGTON, D. C.

SEPTEMBER 21 TO OCTOBER 12, 1908

By the authority of

HIS EXCELLENCY, EDWIN S. STUART

Governor of the Commonwealth

SAMUEL G. DIXON, M. D., Commissioner of Health

OUTLINE.

The present plan of the State governmental anti-tuberculosis work in Pennsylvania which has been made possible by the liberal appropriation of the Legislature in 1907, with the approval of His Excellency, the Governor, and the details of which are illustrated in this exhibit may be summarized under the following headings:

1. The collection and tabulation of statistics relating to tuberculosis, through official morbidity and mortality reports of each individual case.

2. The establishment of one or more sanatoria for the treatment of incipient cases, including infirmaries for advanced and hopeless cases.

3. The establishment of dispensaries in each county of the State for the care of cases which can not avail themselves of sanatorium treatment, including home visitations and the study of occupational conditions.

4. The maintenance of pathological laboratories for the free examination of sputum and tuberculous lesions, and biological laboratories for the possible development of immunitive and curative products.

5. The restriction of tuberculosis by the disinfection of rooms, buildings (private and public), conveyances and carriers, and by supervision and regulation over the general avenues of infection.

6. The dissemination of knowledge relative to the communicability, care and prevention of tuberculosis.

EXHIBIT NO. 1.

CHART SHOWING THE NUMBER OF DEATHS FROM TUBERCULOSIS AS COMPARED WITH OTHER PRINCIPAL CAUSES OF DEATHS FOR THE YEAR 1907.

The total number of deaths from tuberculosis in all forms was 10,825 and, as shown on the chart, no other single affection contributed so extensively to the death rate.

The registration of vital statistics throughout the entire State of Pennsylvania was commenced January 1, 1906, and therefore, no reliable data for individual years exist prior to that time. The deaths from tuberculosis in 1907, compared with the deaths in 1906, are as follows:

1906	10,780
1907	10,825

The rates per 100,000 of population for the corresponding periods are as follows:

1906	155.5
1907	154.0

The forms of tuberculosis represented in the total and the number of deaths credited to each form are as follows:

Lungs	9,317
Larynx	99
Meninges	525
Abdomen	451
Pott's Disease	82
Abscess	10
White Swelling	41
Other Forms	107
General	193

EXHIBIT NO. 2.

MAP OF PENNSYLVANIA SHOWING THE DEATH RATE FROM TUBERCULOSIS PER 100,000 OF INHABITANTS FOR EACH COUNTY, AND BY SHADED AREAS THE COMPARATIVE RATES ACCORDING TO FOUR PRINCIPAL GROUPS, VIZ:

Under 100, per 100,000.
100 to 125, per 100,000.
125 to 150, per 100,000.
Over 150, per 100,000.

When this exhibit is studied in connection with Exhibit No. 7, which contains the population for each county, it will be noted that with few exceptions the highest death rates correspond to the areas with the greatest density of population. Franklin county with a low density and high death rate contains the State Sanatorium for tuberculosis which necessarily adds to the deaths. Aside from this, however, there is a tendency not only in this but in some other mountainous counties to intermarry, with a consequent physical deterioration which predisposes to tuberculosis. The high rate of Montour, a county small in area, is due to the inclusion of a State Insane Asylum with a high tuberculosis death rate.

The relatively high rates of Pike, Montour and Wayne are due to the large number of tuberculosis persons who seek the mountains of this section for purpose of cure, many of whom come from New York City. Luzerne county is the seat of the "Free Hospital for Consumptives" at White Haven, and Carbon county contains a number of small private sanatoria.

EXHIBIT NO. 3.

CHART SHOWING THE DEATHS FROM TUBERCULOSIS BY AGE PERIODS.

The impressive feature of this chart is the fact that tuberculosis finds the greatest number of its victims in early adult and middle life, the most productive and, therefore, the most valuable period.

EXHIBIT NO. 4.

CHART SHOWING THE ANNUAL COST OF TUBERCULOSIS TO THE STATE AND TO THE PEOPLE THEREOF.

In computing the cost of tuberculosis each life has been estimated at three thousand dollars. The loss of earning power of the living cases has been estimated at seven and one-half dollars per week for one year; the expenditure attendant upon treatment and burial of each dying case at one hundred dollars; and the expenditure for special foods, medicines, medical attendants and nursing of each living case at fifty dollars. To these amounts has been added the actual money appropriated by the State and its municipalities, to be devoted exclusively to tuberculosis work, but no account has been taken of private contributions for such work.

When it is considered, as shown in Exhibit No. 3, that the greatest number of deaths from tuberculosis occur in early adult and middle life, the economic value ($3,000.00) placed upon each death is very conservative. The majority of sociologists are inclined to place this figure higher ($5,000.00).

EXHIBIT NO. 5.

CHART SHOWING THE AMOUNT APPROPRIATED BY THE STATE OF PENNSYLVANIA EXCLUSIVELY FOR TUBERCULOSIS WORK FROM 1893 TO THE PRESENT TIME.

The year 1893 marks the date of the first State appropriation for tuberculosis work. The amounts appropriated at each biennial session of the Legislature since that date and the institutions receiving the same are as follows:

1893—Rush Hospital for the Treatment of Consumption and Allied Diseases, ... $10,000.00

1895—Rush Hospital for the Treatment of Consumption and Allied Diseases, ... $10,000.00

1897—Rush Hospital for the Treatment of Consumption and Allied Diseases, ... $10,000.00

1899—Rush Hospital for the Treatment of Consumption and Allied Diseases, ...$10,000.00
1901—Rush Hospital for the Treatment of Consumption and Allied Diseases, ...$10,000.00
Free Hospital for Consumptives, White Haven, ...$50,000.00
1903—Rush Hospital for the Treatment of Consumption and Allied Diseases, ...$47,000.00
Free Hospital for Consumptives, White Haven, ...$115,000.00
State Forestry Commissioner, ...$8,000.00
1905—Rush Hospital for the Treatment of Consumption and Allied Diseases, ...$50,000.00
Free Hospital for Consumptives, White Haven, ...$70,000.00
State Forestry Commissioner, ...$15,000.00
1907—Rush Hospital for the Treatment of Consumption and Allied Diseases, ...$50,000.00
Free Hospital for Consumptives, White Haven, ...$70,000.00
Pittsburg Sanatorium, ...$15,000.00
Grand View Sanatorium, ...$7,000.00
West Mountain Sanatorium, ...$5,000.00
State Department of Health, ...$1,000,000.00

EXHIBIT NO. 6.

MAP OF PENNSYLVANIA SHOWING THE DIVISIONS OF THE STATE INTO SEVEN HUNDRED AND THIRTY-THREE SANITARY DISTRICTS.

In each sanitary district a Health Officer is maintained by the State to whom cases of communicable disease, including tuberculosis, are reported by physicians. These officials disinfect premises occupied by tuberculosis sufferers or in which patients have died from tuberculosis; also school-rooms and other public places frequented by them.

The care and management of every case of communicable disease occurring outside the limits of incorporated municipalities devolves upon the State Department of Health. A County Medical Inspector is in direct supervision over the work of the Health Officer in each county of the State.

EXHIBIT NO. 7.

MAP OF PENNSYLVANIA SHOWING THE LOCATION OF DISPENSARIES FOR THE FREE TREATMENT OF TUBERCULOSIS IN EACH OF THE SIXTY-SEVEN COUNTIES, EMBRACING AN AREA OF 46,017 SQUARE MILES AND A POPULATION OF 6,928,575.

The first dispensary was opened July 22, 1907, at Wilkes-Barre, and the last at Greensburg, June 2, 1908. As noted, the number of cases under treatment during July 1908, was 3,472. Each dis-

pensary is in charge of a chief physician, from one to thirteen assistants, one to five nurses according to the number of patients under treatment, and is open at convenient hours, day or evening, to accommodate the occupational demands of those who are able, or who are compelled to work. The location has been determined with a view of reaching the most populous centers. The great object of the dispensary is to reach each individual indigent case of tuberculosis, and by competent medical advice, treatment and supervision ameliorate or entirely relieve their physical condition, and at the same time educate them as to the communicable character of their disease to the end that others may not become infected through ignorance or carelessness. The dispensary nurses are required to make visits to the homes of dispensary patients and advise as to the methods of personal hygiene and home sanitation; instruct non-affected persons of the household as to the dangers, and how to avoid infection; to spread the doctrine of fresh air, sunlight, rest, proper foods, temperate habits and obedience to the instructions of the medical advisors; at the same time discover unsuspected cases. 3,006 such visits were made by dispensary nurses during July, 1908. The occupational pursuits of those who are compelled to work are likewise investigated, and visits are paid to factories and workshops where consumptives are employed, in order that unhygienic surroundings may be bettered, and the safety of co-workers as well as the users or consumers of the manufactured products be preserved.

It is from these dispensary patients that the inmates of the State Sanatorium are largely recruited.

The equipment of the dispensary consists of a suite of rooms centrally located, and supplied with only such furniture as is absolutely necessary for the work to be done. The rooms vary in number according to the number of patients under treatment, and their arrangement must conform with modern sanitary ideas, no pains being spared to keep them in such a condition of cleanliness as to furnish an object lesson to all who may visit the dispensary. The furniture consists of a filing cabinet, tables, chairs, examining stools, couch, scales, toilet set and a few instruments for measurements of the chest and simple examinations of the nose and throat. It is of simple, plain design, and was selected with a view to efficiency and economy.

Dispensary records are kept upon blank forms provided by the Department, and frequent inspection by an officer from Department Headquarters insures proper recording of the desired information. The inspecting officer also pays careful attention to the physical and sanitary condition of the dispensary rooms.

In all the larger dispensaries the "Class System" has been inaugurated. Under this system classes are organized among the patients, each of which contains not over twenty-five members. The number of classes varies, being governed by the needs of the individual dispensary. The classes meet at regular intervals, some weekly but usually every two weeks. The members are instructed to take and record their own temperature, pulse and respiration. This they do as frequently as the class leader may direct. Not only do the patients record these particulars but they are also instructed to make careful notes of their condition, feelings and actions. Memorandum books are supplied for this purpose.

At the class meeting patients are encouraged to converse among themselves and compare notes as to their experiences. The note books are submitted to the inspection of the class leader, who carefully reviews each one. Faults are pointed out, and misfortunes discussed, with a view of avoiding their repetition and minimizing unfavorable consequences. Often the ingenuity of one patient will be of great assistance in solving the difficult problem of another. Patients are weighed and the result commented upon.

Indigent dispensary patients are supplied with nitrogenous food stuffs. In addition to food supplies the dispensaries furnish liberal quantities of paper napkins and bags, pressed paper sputum cups for use in tin forms, and pocket cuspidors.

Earnest effort is made through the dispensaries to educate the people in each community to a sense of the value of thorough room disinfection. The Department's Health Officers, of whom there are over seven hundred districted throughout the State, are instructed in the work of disinfection and supplied with the necessary equipment. A postal card sent to any Health Officer will secure his speedy attention. Not only the dispensary physicians, but every practitioner in Pennsylvania is provided with a list of the names and addresses of the Health Officers located in his own and adjoining counties. That the people are becoming aroused to the protection offered them by this procedure is evident from the continually increasing number of requests for disinfection that are pouring in upon the Department of Health and its officers.

In a number of instances the members of the staff, at a particular dispensary, have associated themselves together as a society for the better study of their cases. This action has occurred in no less than nine different counties, and in a number of these the societies meet not only for discussion and study by the members themselves, but other physycians not connected with the dispensary are invited to be present at the meetings and to take part in the work of the society. The spirit of friendship thus fostered among the physicians of a community is of value beyond question, not only to the physicians themselves, but to the community at large.

EXHIBIT No. 12.

RELIEF MODEL OF GROUNDS AND BUILDINGS OF THE PENNSYLVANIA STATE SOUTH MOUNTAIN SANITORIUM.

This reservation comprises 650 acres and is located in Franklin county near Mont Alto on a plateau of the Blue Mountains with an average elevation of about 1,800 feet above the sea level. Its topography and climatic conditions render it particularly well adapted for the treatment of tuberculosis, while its geographical location makes it readily accessible from all parts of the State. This Sanatorium had its inception in an appropriation by the Legislature of Pennsylvania in 1903 of the sum of $8,000.00 to the Commissioner of Forestry, to be used for the treatment of tuberculosis sufferers, and a further appropriation in 1905 of $15,000.00.

The lands devoted to the purpose were a part of a large area (55,000 acres) which had been purchased by the State for a forest reservation. Upon this a number of small shacks were erected, and on June 1st, 1907, at which time its management and control were transferred to the Pennsylvania State Department of Health, 28 patients were under the care of the Forestry Commissioner. The area is sufficiently large to afford a scheme of development which will permit the classification and segregation of patients of different types or degrees of infection, if so desired, and also to supply light open air employment to those physically capable of performing the same, while the large State forest reservation adjacent insures the Sanatorium from all undesirable surroundings. The water supply is collected from mountain springs on the State reservation. The spring heads are all walled over that they may not be exposed to any pollution. The water is then carried in cast-iron pipes to a pumping well and from there it is forced into a large reservoir with sufficient capacity to supply the entire camp with water for two months in case of drought. The height of the reservoir is sufficient to give ample pressure in case of fire. The ice is collected from an ice dam and sufficient storage capacity is provided in an ice house to meet all requirements. The assembly building serves the purpose for general meetings and a chapel for religious services. The barn is constructed of stone and frame with slate roof and affords accom-

modation for 16 head of mules and wagon room for as many vehicles. The ground applicable for farming comprises an area of about 100 acres. The accommodations as shown on this model provide for five hundred patients.

EXHIBIT No. 13.

PANORAMIC VIEW OF SOUTH MOUNTAIN RESERVATION SHOWING THE GROUP OF SANITORIUM BUILDINGS IN THE DISTANCE.

This photograph shows the large area of forest in which the camp is located and the manner in which it is protected by natural conditions.

EXHIBIT No. 14.

PANORAMIC VIEW SHOWING SOME OF THE ORIGINAL SHACKS AND THE CONSTRUCTION OF NEW COTTAGES, PAVILIONS, BATH-HOUSES, ETC.

This photograph taken from the roof of the Administration Building, gives a good view of the general construction work in the camp.

EXHIBIT No. 15.

PANORAMIC VIEW OF THE MOUNTAINS FROM ROCKY POINT NEAR SANATORIUM.

The slightly undulating character of the Reservation affords opportunity for graded exercise of the patients while the beauty of nearby forest and distant mountains is always grateful. "Green battlements that guard the Health Port of the South Mountain Sanatorium." *Leigh Mitchell Hodges.*

EXHIBIT No. 16.

PANORAMIC VIEW OF PART OF THE OLD CAMP.

This shows a view of a part of the old camp site started in 1902. Here was built the first little cabin 8 x 8 feet, constructed out of second-hand lumber. From this cabin, which is still in use, grew the present camp, which is laid out on a scale to ultimately accommodate 4,000 people.

EXHIBIT No. 17.

PANORAMIC VIEW OF SEWAGE DISPOSAL PLANT.

The sewage disposal works comprise settling basins designed to be operated as settling tanks if desired, sprinkling filters, intermittent filters and a chemical sterilizing chamber. The object of the

works is to completely change the sewage into a pure water by the absolute destruction of all organic matter in the sewage. The plant operates by gravity. It is provided with automatic mechanism to simplify the duties of the caretaker. The site has been chosen remote from the camp and all the buildings, and the layout is adapted for additions capable of handling the sewage of a population of 4,000 people.

EXHIBIT No. 18.

MOUNTAIN VIEW NEAR THE CAMP.

"The pine clad mountains as seen from Pennsylvania's 'Hillside City of Hope.'" *Leigh Mitchell Hodges.*

EXHIBIT No. 19.

PHOTOGRAPH OF MODEL COTTAGE FOR INCIPIENT CASES.

(See description under Exhibit No. 26.)

EXHIBIT No. 20.

PHOTOGRAPH SHOWING THE RELATIVE POSITION OF COTTAGES, THE CORNERS OF WHICH CORRESPOND TO THE FOUR POINTS OF THE COMPASS.

This picture shows how the positions of the cottages are arranged so that no two cottages in adjacent rows come directly opposite each other .

This scheme gives more air space than if two adjoining rows were built with the cottages directly opposite, and also prevents them from throwing shadows on each other. By having the corners of the square cottages pointing to the four points of the compass the four sides and windows get the maximum sunshine during the entire year.

EXHIBIT NO. 21.

ADMINISTRATION BUILDING AND STATION TEAM.

This building is used for offices.

The team of mules represents the style of conveyance used to transport passengers from the railroad station to the Sanatorium.

EXHIBIT NO. 22.

PART OF THE MEDICAL AND NURSING STAFF.

This picture shows some of the physicians and nurses of the Pennsylvania State South Mountain Sanatorium in their uniforms.

EXHIBIT NO. 23.

GROUP OF PATIENTS IN WHOM THE DISEASE HAS BEEN ARRESTED.

EXHIBIT NO. 24.

ONE OF THE PRESENT CHICKEN-HOUSES.

The care of poultry has proven an interesting occupation for patients who are physically able to perform light work. A supply of fresh eggs will be provided when the chicken house now under construction, is completed. The house will be 450 feet long with provision for the housing and yarding of chickens in lots of 25. A house for the keeper and one for storing and preparing food will also be provided.

EXHIBIT NO. 25.

WHITE PINE FOREST ADJOINING CAMP.

This beautiful grove of pines is used for park purposes by the patients. With its lofty canopy of evergreen foliage and its underlying carpeting of pine needles upon which the footfalls are noiseless, it had been christened by the patients who enjoy its stately aisles, as the "Cathedral Pines."

EXHIBIT NO. 26.

MODEL OF COTTAGE FOR INCIPIENT CASES.

The cottages are one story in height with a liberal air space between the ceilings and the roofs to guard against the extreme heat of summer and the extreme cold of winter. The floorings are double with water proof material between.

The first floor is divided into four rooms opening into an entryway widened in the centre by adding space from the corners of the rooms. The entryway has a door at each end, which permits a free circulation of air to blow past the four door ways leading into the rooms Each door has a transom over the top which is open at all times in case a door should be closed for any special purpose. In the middle of summer and the extreme cold of winter. The floorings are double larger pipe which opens into the entry at the ceiling, so that the warmer air of the cottage can be freely forced into the colder outside atmosphere, thereby making a gravity ventilation. Each room has two large windows with sash hung on ball bearing rollers, so that they can be pushed back, leaving the entire window space open. The eaves overhang only four inches so as not to throw any shad-

ows on the sides of the buildings. This gives the cottages the maximum of sunlight. This construction would not protect the open windows from rain and snow during heavy storms. To provide against such storms wide shutters are hung with rollers on tracks so that they hang vertically against the walls in fair weather. They can be pulled over the windows with perfect ease during a storm, and fixed at any angle desired by an arrangement of hooks, thereby permitting of a free circulation of air. The floors average about 18 inches above the ground, leaving an open space for the air to circulate under the cottages during fair weather. Solid shutters, however, are arranged which drop over the spaces, entirely closing them during heavy rain or snow storms. This model is constructed on a scale of 1 inch equal to 1 foot, the original cottages being 27 feet square, constructed of wood with foundation piers of concrete, and roofs of fire-proof asbestos and cement shingles.

EXHIBIT NO. 27.

MODEL OF OPEN AIR PAVILION.

The pavilions are constructed of wood with concrete pier foundations. The roofs are built of fire-proof shingles made of asbestos and cement. The buildings are entirely open with the exception of a wall extending three feet above the floor. The eaves overhang only four inches so as to permit of the maximum sunlight. Awnings are arranged so as to drop in time of heavy rain or snow storms. These, however, will only be closed on the stormy side, leaving at least, two sides open during bad weather. The floor is 36 feet by 24 feet, which will permit of two rows of reclining chairs for the patients during the daytime. The width is sufficient to permit of a liberal aisle between the rows of chairs. These pavilions are to take the places of porches around the cottages, which would cut off the sunlight.

EXHIBIT NO. 28.

MODEL OF TENT.

This model, on a scale of 1 inch equal to 1 foot, was made by Mr. John Quicksell, a patient. Tents of this type are used for the stronger patients during the entire year, where they keep perfectly comfortable during the coldest weather in the winter.

EXHIBIT NO. 29.

CHART, FRONT AND SIDE ELEVATION OF DINING HALL.

The kitchen and dining room is constructed of concrete and frame with asbestos roof. It will now accommodate 500 patients, and is so planned as to permit of extensions which will seat 1,000 patients.

EXHIBIT NO. 30.

CHART, FIRST FLOOR, PLAN OF DINING HALL.

There is a half basement which provides cold storage and all other accessories necessary for kitchen and dining room purposes, such as butcher shop, storage and heating plant.

EXHIBIT NO. 31.

CHART, SECOND FLOOR, PLAN OF DINING HALL.

The quarters for help are arranged in the second story over the dining hall, well heated and ventilated, and so situated as to have sunlight in each of the rooms, which accommodate in all 100 people.

EXHIBIT NO. 32.

CHART, FRONT, SIDE AND REAR ELEVATIONS OF INFIRMARY.

The infirmary for the accommodation of the incurable cases is beautifully situated in the pines. It is constructed of concrete and wood, with a fire proof asbestos and cement roof. It has all the necessary modern accommodations of a hospital building, with a wing to accommodate the nurses and help. The elevation of the building represents a long narrow construction two and one-half stories high, so as to permit of plenty of air and sun in all the small wards. It has indirect heating apparatus and ventilation. The present construction will accommodate 110 patients, and is so planned as to permit of extensions for 200 patients.

EXHIBIT NO. 33.

CHART, FIRST FLOOR PLAN OF INFIRMARY.

EXHIBIT NO. 34.

CHART, SECOND FLOOR PLAN OF INFIRMARY.

EXHIBIT NO. 35.

CHART, ELEVATION AND FIRST AND SECOND FLOOR OF LAUNDRY.

The laundry building is constructed of wood, concrete and asbestos shingles. It is provided with sterlizing washers arranged so that the clothing can be placed in the revolving washers from the receiving room, taken out sterilized and washed, into another room where the laundresses receive them to carry them through the drying and ironing machinery. Accommodations for the necessary help are provided on the second floor.

EXHIBIT NO. 36.

CHART, ELEVATION AND FLOOR PLANS OF OPEN AIR PAVILIONS, BATH-HOUSE, TOILET BUILDINGS AND COTTAGES.

(For model of open-air pavilion see Exhibit No. 27.)

The camp is provided with bath houses constructed of wood with concrete foundations and fire-proof roofs. Each house is divided off into twelve little dressing rooms with a hand shower-bath room adjoining. They are all provided with a comfortable waiting room for the use of the patients after bathing. The buildings are well heated with sufficient ventilation and yet not enough to chill the bathers by causing too rapid an evaporation when wet. The toilet houses are substantially built of wood, concrete and fireproof roofs and are conveniently situated for the use of the patients. They are all provided with water closets and connected with the sewage system, the effluent of which is pure enough to drink.

EXHIBIT NO. 37.

PHYSICIAN'S DISPENSARY COAT.

This garment is a sample of the coat supplied for use of physicians in attendance at the dispensaries. It is washable and in each case is long enough to fully cover the other clothing worn by the physician. In this way the physician avoids the danger of carrying infection from the dispensary to outside patients.

EXHIBIT NO. 38.

DISINFECTOR'S SUIT.

This suit is used by the Health Officers when disinfecting houses so that they may not carry the infection from place to place.

EXHIBIT NO. 39.

THE DEPARTMENT'S DISINFECTING APPARATUS.

Each of the State Department of Health's 733 Health Officers is provided with a disinfecting apparatus that is used in fumigating rooms and premises that have been occupied by a case of communicable disease. The apparatus consists of a tin pan measuring 15 inches in diameter at the top, 11 inches at the bottom, and with a depth of five inches, and a large funnel-shaped container measuring 15 inches in diameter at the top, 11 inches at the bottom, the inside depth of the flaring part being 5 inches, and the depth of the lower part 6 inches. The dimensions of the vessel have been fixed by empirical trial as ample for the diffusion of the gas, preventing its

ignition when in contact with a live flame. The pan within which water is placed interlocks with the container proper leaving sufficient space between the vessels for the circulation of water which protects the floor from heat generated by the chemical action. For convenience in carrying the pan is made to rest in the top of the container. Eight ounces, by weight, of commercial potassium permanganate crystals is required for each pint of the officinal (U. S. P.) solution of formaldehyde in disinfecting every thousand cubic feet of air space and 24 ounces of potassium permanganate may be safely used in this vessel without danger of overflow.

EXHIBIT NO. 40.

NURSE'S DISPENSARY GARB.

A sample of the apron or gown provided for the use of nurses and women physicians in attendance at the dispensaries. It is washable and protects the clothing. It is designed to avoid the danger of carrying infection from the dispensary to outside patients.

EXHIBIT NO. 41.

SPUTUM CUPS.

First, tin form and filler for home use. This sputum cup is a combination of a tin form provided with a handle and cover, the cover kept in place with a spring and the paper filler. The latter, properly folded, is put into the form, making a receptacle easily handled and stable enough to be allowed to stand upon the table at the bedside or near the patient's reclining chair. When full or soiled this paper filter can be pushed out of the tin form directly into the fire of a stove or furnace, in this way providing easy and certain disinfection. The tin form can be boiled.

Second—Pocket Sputum Cups. These cuspidors are for use by the patient when away from home. The entire cuspidor is destructible by fire. The paper has undergone a waterproofing process.

EXHIBIT NO. 42.

LABORATORY OUTFIT FOR SPUTUM EXAMINATION.

This outfit is used by the physician to mail sputum, other excretions and tuberculous lesions, to the Pennsylvania State Laboratory for examination.

EXHIBIT NO. 43.

ANTI-SPITTING SIGN.

Adopted by the Department for the Dispensaries and Sanatorium.

EXHIBIT NO. 44.

BIOLOGICAL PRODUCTS.

The possibility of developing a biological product which would have an immunizing and curative influence in tuberculous infection, engaged the attention of Dr. Samuel G. Dixon, the Commissioner of Health, prior to 1889, in which year in an article in the "Medical News," date of October 19, branched forms of tubercle bacilli were noted and two hypotheses presented as to the establishment of tolerance together with results obtained by inoculation. The two products here shown, No. 5, a suspension of dead tubercle bacilli and No. 10, a salt solution extract from living tubercle bacilli are the result of extensive experiments upon the subject, and at the present time are being used in certain types of cases. The results which are apparently favorable are being tabulated for publication as soon as they reach a number sufficiently large to warrant definite conclusions being drawn. The literature presented by Dr. Dixon upon the subject may be found under Exhibit No. 84.

LABORATORY METHODS CONCERNING THE BIOLOGICAL PRODUCTS.

1. Method of Production.
2. Method of Standardization.
3. Method of arriving at dosage.

Action of the two products toward one another.

No. 5.—DEAD TUBERCLE BACILLI.*

1 and 2. Method of Production and Standardization.

After the bacillary mass is removed from the filtrate it is dried of excess moisture, over night, perhaps, in the incubator, and then it is dried in the vacuum desiccator over sulphuric acid until it becomes brown and brittle. The masses are then broken into small fragments and placed in a soxhlet. An equal quantity by weight of human and bovine bacillary mass is used. The first extraction is done with absolute alcohol and is continued until the brown color of the distillate has disappeared. The alcohol is then replaced by ether and the extraction is continued until the cooled ethereal distillate is practically clear. Absolute clearness is impracticable to obtain because it seems impossible to extract all fat and wax from the tubercle bacillus. Vandremer and Martin say that six weeks extraction with petroleum ether will not remove all the fat. The extraction necessary to bring about the above result

*"Possibility of establishing tolerance for the Tubercle Bacillus," Medical News, Oct. 19, 1889.

will last six to eight days of nine hours each, depending upon the size of the clumps. When the ether extraction is complete, the mass is dried twenty-four hours at 45 deg. C. The resulting mass consists of dirty yellow gray granules which break up easily into a slightly greasy powder. This is not soluble in water, salt solution, alcohol or ether and when used must be ground up in definite quantity and the per volume weight is determined. The usual method is to grind up a large quantity, without previous weighing, in a ball mill with a small quantity of salt solution. A definite quantity of this suspension, say 20 cubic centimeters, is evaporated to dryness in a tared watch crystal and the same quantity of the salt solution used to make the suspension is also evaporated. The difference in these weights will equal the weight of the diseased organisms in amount of suspension used. In order that the emulsion shall be homogeneous, the suspension after grinding is centrifuged the supernatant liquid removed and resedimented in the machine. After a third centrifugalization one obtains a homogeneous emulsion which will stand without sedimenting for a long while. Any slight sediment which occurs after three or four weeks will shake up into perfect homogeneity. 8.64 milligrams to the cubic centimeter is the highest strength heretofore obtained in perfect emulsion. The salt solution used is .6 per cent.

The microscopic examination of the mass after extraction shows chiefly unbroken organisms which takes the acid fast staining methods very faintly but clearly. The irregularity of staining characteristic of the tubercle bacillus is more pronounced. Careful observation with high objectives and oblique light shows no irregularity in the contour of the single cell but the edges of the stained portions seem more irregular than the untreated bacillus.

Microscopic examinations of the ground emulsion shows many fragments chiefly single organisms and only occasionally two, never more, clinging together. The staining is apparently the same as before grinding.

3. Method of dosage and toxicity. The difficulty of expressing the value of these products in any unit of toxicity or other property has compelled the adoption of a dose which when repeated every week or ten days causes no loss of weight in healthy or tuberculous guinea pigs of 400 to 600 grams. It is not necessary to give all the details of the primary experiments, but it will be enough to state that weekly injections of .000001 gram of the organisms are withstood without loss of weight. Of the later experiments three pigs received twenty-three injections of the product before injections of the organisms. They still live. They have gained from 350 to 600 grams in nine months and have lost no weight since the injections of the organisms.

No. 10.—TUBERCLE BACILLI EXTRACT.*

1 and 2. Method of Production and Standardization.

This product is made from living organisms removed from fluid media. An equal weight is taken from human and bovine stains, dried of excess water in the incubator and then washed in an excess of ether. This is renewed when it has removed the last remnants of water and glycerin and the second portion allowed to act six hours to soften the wax of the organisms. This fat separates so that it collects at the bottom of the vessel and may be removed by a Pasteur pipette. After removing the second ether, the mass is allowed to dry until no more ether odor is perceptible. Then the separated fat is removed. The mass is weighed, ground thoroughly in a mortar and suspended in ten parts of .6 per cent. salt solution. This suspension is carried in a shaking machine eight hours and allowed to stand sixteen hours at room temperature. It is then filtered several times through porcelain, the filtrate being a light amber or pronounced straw colored fluid, the product No. 10. The standardization of the extract must depend upon its equivalent in tubercle bacilli. One cubic centimeter represents the extract of .1 gram of the organisms. Repeated microscopical examination of the sediment of large quantities fails to reveal any bacteria and injections of a single large or repeated small dose do not produce tuberculosis.

The following is a chemical analysis of the product No. 10:

	Human.	Bovine.
Color,	Deep straw yellow,	Straw yellow.
Reaction,	Faintly acid,	Faintly acid.
Total residue,	1.27 per cent.,	1.23 per cent.
Sodium chloride,	0.74 per cent.,	0.68 per cent.
Organic matter,	0.46 per cent.,	0.44 per cent.
Sulphates,	Slight,	Slight.
Calcium,	Slight,	Slight.
Odor or residue on evaporation,	Slightly ammoniacal,	Slightly ammoniacal.
Color tests of residue with strong acids and alkalies	None,	None.
Tanret's test for albumens,	Positive,	Very faint.
Trichloracetic acid test for albumens,	Positive,	Faint.
Salicysulphonic acid test for albumens,	Negative,	Negative.
Nitric acid and heat test for albumens,	Negative,	Negative.
Mayer's reagent for alkaloids,	Negative,	Negative.
Alphanaphthol test for carbo-hydrates,	Faint,	Negative.
Nessler's test for ammonium compounds,	Strong,	Positive.
Ammonium molybdate test,	Positive,	Positive.
Tannic acid test,	Very faint turbidity,	Very faint turbidity.

Effect of sensitization for one another.

Each of these products will sensitize for itself but the experiments show that one injection of No. 5 will not sensitize for a subsequent dose of No. 10. The reverse is also true.

*Same as "Fluid of Dixon," Medical News, Jan. 17, 1891.

This last observation, viz: Of the effect of the alternate use of Dead Bacilli No. 5, and the Extract of Living Bacilli No. 10, in healthy animals was made by Dr. Herbert Fox.

EXHIBIT NO. 45.

PHOTOGRAPHS OF PATHOLOGICAL LABORATORIES.

These pictures represent the Laboratories of the University of Pennsylvania where the Pennsylvania State Department of Health conducts its bacteriological and chemica work, which consists of original research work, examinations of pathological specimens for diagnostic purposes and examinations of water for purity, largely used by the Sanitary Engineering Division of the Department.

EXHIBIT NO. 46.

PHOTOGRAPHS OF PATHOLOGICAL LABORATORIES.

EXHIBIT NO. 47.

PHOTOGRAPHS OF STATE CAPITOL.

In which the general offices of the State Department of Health are located.

EXHIBIT NO. 48.

FLOOR PLAN OF CAPITOL BUILDING SHOWING THE LOCATION AND SPACE OCCUPIED BY THE DEPARTMENT OF HEALTH.

EXHIBIT NO. 49.

PHOTOGRAPH OF MACHINE USED IN TABULATING STATISTICS OF MORBIDITY AND MORTALITY.

EXHIBIT NO. 50.

CARTO-GRAPHIC DISPLAY IN LEAF CABINET.

Copy of the Act of Assembly creating the Department of Health and empowering it to make rules and regulations concerning communicable diseases. It is under the authority conferred by this Act that tuberculosis is made a reportable affection.

EXHIBIT NO. 51.

(A) A copy of the rules and regulations of the Department of Health making tuberculosis a reportable affection and specifically prescribing the methods of reporting both in municipalities and rural sections.

(B) Report cards supplied to physicians for the purpose of reporting tuberculosis occurring in rural districts to Health Officers. These reports are in turn forwarded to the State Department of Health, with additional reports as to any action taken by the Health Officer. Upon their receipt in the Department of Health they are filed for future reference according to locality and are tabulated for statistical purposes.

EXHIBIT NO. 52.

Copies of blanks supplied to Boards of Health in municipalities and to institutions for making returns of communicable diseases, including tuberculosis, to the Department of Health. Under the regulations as set forth in Exhibit No. 45, Boards of Health in municipalities and institutions are required to report at the end of each week all cases of communicable diseases which have been reported to them by physicians. Upon receipt of these reports in the Department of Health they are filed for reference according to locality and tabulated for statistical purposes.

EXHIBIT NO. 53.

(A) Copies of cards requesting Health Officers to disinfect premises upon the removal or death of the tuberculous occupant. These cards are supplied to physicians for the purpose of making requests for disinfection of premises.

(B) Form 37 is the card upon which the local Health Officer advises the County Medical Inspector of the disinfection of any premises within his jurisdiction.

(C) Form 38 is a certificate of disinfection which is issued by Health Officers to the owner or occupant of the premises which have been disinfected for any purpose.

EXHIBIT NO. 54.

Copy of directions issued by the Department of Health for room disinfection following cases of communicable diseases, including tuberculosis, either by formaldehyde gas or sulphur. A room is taken as the unit of house disinfection.

EXHIBIT NO. 55.

A copy of the Act of Assembly appropriating the sum of $600,000 for the establishment of tuberculosis sanatoria and $400,000 for the establishment of dispensaries.

EXHIBIT NO. 56.

(A) Request cards for supplies for dispensaries.
(B) Card index file of dispensary patients.
(C) Notice to dispensary of change of residence.
(D) Notice to patient to call at dispensary for examination for admission to State Sanatorium.
(E) Result of examination for admission to State Sanatorium.
(F) Health Officer's and nurses's weekly report to dispensary of visits to tuberculosis stations.

EXHIBIT NO. 57.

(A) Application blank for treatment at tuberculosis dispensary.
(B) Tuberculosis dispensary card.
(C) Individual history and examination records of dispensary patients.

EXHIBIT NO. 58.

(A) Dispensary examination blank for throat, nose and ear.
(B) Health Officer's and Nurse's report.
(C) Detailed report of inspections and visitations.

EXHIBIT NO. 59.

(A) Physical diagnosis chart of dispensary patients.
(B) Record of treatment and condition of dispensary patients.

EXHIBIT NO. 60.

(A) Dispensary monthly report of new patients.
(B) Detailed monthly dispensary report.
(C) Order for supplying milk to dispensary patients.
(D) Acknowledgment of supplies received at dispensary.

EXHIBIT NO. 61.

(A) Application for admission to sanatorium.
(B) Index card of waiting list for sanatorium.
(C) Index card for inventory of personal property.
(D) File index card for sanatorium patients, and reverse of same.

EXHIBIT NO. 62.

(A) Individual history and examination record of sanatorium patients.
(B) Sanatorium examination blank for nose, throat and ear.

EXHIBIT NO. 63.

(A) Physical diagnosis chart for sanatorium patients.
(B) Notes, treatment and diet chart for sanatorium patients.

EXHIBIT NO. 64.

(A) Weekly case record of sanatorium patients.
(B) Reverse of same.

EXHIBIT NO. 65.

(A) History chart for sanatorium cases.
(B) Inspection chart for sanatorium cases.

EXHIBIT NO .66.

(A) Monthly report of new patients admitted to sanatorium.
(B) Detailed monthly report of sanatorium.

EXHIBIT NO. 67.

(A) Report of a case of tuberculosis on individual report card.
(B) Punch card for tabulating statistics from card (A).
(C) Certificate of death from tuberculosis of the lungs.
(D) Punch card for tabulating statistics from certificate (C).

AUTOCHROMES.

The development of color photography has afforded an opportunity to perpetuate the colors contained in fresh pathological specimens.

The color plates shown, were made from specimens immediately after autopsy, and are, therefore, free from the bleachings and contractions which take place in preserved specimens. While the entire process may be considered more or less in its infancy, the results forecast that color photography will have an important place in pathological studies.

EXHIBIT NO. 68.

Photograph No. 1.

VIEW OF THE COSTAL SURFACE OF LEFT LUNG OF A CASE OF CHRONIC ULCERATIVE TUBERCULOSIS WITH CAVITY FORMATION.

This photograph shows irregular areas of thickened pleura over the upper lobe, with tabs of torn adhesions especially along the fissure. The anterior inferior portion of the upper lobe is solid with conglomerate tubercules. The upper part shows a few scattered caseous tubercules. The lower lobe shows hypostatic congestion with

diffuse grayish thickening of the pleura, and a few caseous tubercles. The apex is the seat of softening perceptible to the touch, with but little evidence of involvement on the pleural surface, whereas the lower interior portion of the same lobe is solid but does not suggest a cavity within. The yellowish, gray and red mottling of the lower half of the upper lobe is due to cheesy-like degeneration of fused tuberculous areas. The individual caseous tubercles may be noted by the pale yellowish dots beneath the pleura in the upper portion of both lobes. The pleural surface of the tissue is apparently uninvolved, except for a few adhesions.

EXHIBIT NO. 69.

Photograph No. 2.

VIEW OF THE INTERNAL SURFACE OF LEFT LUNG SHOWN IN NO. 1, SHOWING ROOT OF SEVERED BRONCHI AND VESSELS.

To the left center are noticed the two openings of the superior and inferior bronchus about the former of which is a large semilunar shaped anthracotic and caseous bronchial gland. To the left of the bronchi is the opening of the pulmonary artery and below and to the right the opening of the distended pulmonary vein. The internal surface does not show the extent of the tuberculosis portion that the costal surface showed in No. 1. The thickened pleura with its torn shreds is visible over the upper lobe (upper left hand corner). The interior surface of the upper lobe just above the superior bronchus and lymph gland shows some thickness due to conglomerate caseous tubercles. The lower internal surface of the upper lobe is more or less emphysematous and the consequent anemia of that portion accounts for the pearliness and lack of color in that area. The portion below and to the right of the large pulmonary vein shows numerous small caseous tubercles. On the lower lobe the pleura has much the appearance of the pleura on the internal surface overlying the area of hypostatic congestion and also shows some scattered individual caseous tubercles. The bluish color over the area of hypostatic congestion is due to extravasted blood and decomposed hemaglobin.

EXHIBIT NO. 70.

Photograph No. 3.

VIEW OF SECTION SURFACE OF SUPERIOR AND INFERIOR LOBES OF RIGHT LUNG, THE MATE OF NOS. 1 AND 2.

In the center of the picture is the partially opened inferior bronchus, running downward and to the right. To the left and upper center is the opening of the pulmonary vein. The upper lobe is

riddled with cavities of various sizes, the largest of which is at the extreme upper left hand corner. Just above the center of the picture are found bronchiectatic dilatations running toward the areas of greatest involvement. The connective tissue is seen to be increased principally at the extreme top of the picture beside the large cavity and on its lower left hand wall. The portions of the upper lobe not occupied by the cavities contain increased connective tissue or are involved in a chronic caseous tuberculosis in the form of large miliary tubercles. The cavity in the upper right hand corner shows no well defined wall but rapid extension into the areas of caseous tubercles. Especially upward the wall is ulcerated and ragged. The large cavity on the left side is lined with a smooth membrane and shows some definite limitations. All of the cavities and bronchi contained large quantities of thick creamy pus which was emptied by the section. On the lower left portion of the upper lobe the pleural covering shows some caseous tubercles shining through. The lower lobe is uniformly congested. In the upper right corner there are a few well defined masses of caseous tubercles. Following the smaller bronchi downward and to the right, spreading out in branch form are pale areas marking the spread of the infection by means of the bronchi. This is in the form of early consolidation around the bronchioles. The large bronchus mentioned first in the description of this lung is the seat of a purulent bronchitis and indicates the course of infection in the bronchioles.

EXHIBIT NO. 71.

Photograph No. 4.

VIEW OF COSTAL SURFACE OF LEFT LUNG SHOWING A MARKED CONDITION OF ANTHRACOSIS.

The tessellated appearance is due to the presence of minute particles of coal in the lymph spaces separating the group of respiratory cells into which they have been carried from the bronchioles or air cells, by cell carriers with this peculiar function. These deposits when present in moderate quantity have no serious effect. In large quantities they destroy elasticity, obstruct lymph flow and impede venous circulation, creating thereby possible emphysema or in the lymph glands a chronic hyperplasia, and establishing a fertile area for tuberculous infection. Coal workers are almost universally affected with anthracosis. The left margin of the specimen shown in photograph is moderately emphysematous, as indicated by its undulating character. The lung as a whole shows slight passive congestion.

EXHIBIT NO. 72.

Photograph No. 5.

SECTION OF RIGHT LUNG SHOWING CHRONIC ULCERATIVE TUBERCULOSIS WITH CASEOUS MASSES IN THE LOWER LOBE.

Above the center of the section is the superior bronchus. At the center and slightly to the right are two branches of the inferior bronchus. There are many round nodules slightly anthracotic over the entire pleural surface. The upper part of the superior lobe shows several caseous areas with a cavity near the right margin which contains yellow pus. The wall of the cavity is smooth. The configuration of the apex on the left is distorted by dimpling of the surface due to a subjacent conglomerate tubercle. In the lower lobe there are a few conglomerate tubercles below and to the right of the branches of the inferior bronchus. There is marked interalveolar anthracosis. This lies chiefly near the bronchi. There are, however, also many smaller areas extending out to the pleura and beneath it.

EXHIBIT NO. 73.

Photograph No. 6.

VIEW OF THE RIGHT LUNG SHOWING EXTENSIVE CASEOUS PNEUMONIA IN THE LATE STAGE IN THE ANTERIOR INFERIOR HALF OF THE SUPERIOR LOBE.

The upper half of the superior lobe shows some of the configuration of the normal lung with conglomerate caseous tubercles shining through the pleura. Note the eroded pleura covering this area. The lower anterior half is solid and there is no respiratory tissue left. The upper part of the lung shows some of the lines of anthracosis marking the lymph spaces. The contour of the upper lobe is destroyed by the mass of exudate on the lower portion. The upper internal portion relatively less involved is not so prominent as the upper anterior portion which has the caseous masses lying beneath the pleural surface. The lower lobe is moderately congested with a large number of caseous tubercles showing through the pleura. A few areas of anthracosis in annular form may be seen in the lower part of the picture. Their centers are pale and here early tubercles are present. In the upper right corner of the lower lobe the caseous portion is seen extending across the fissure and involving the anterior superior border. Alongside of this a hemorrhage and several emphysematous bullae are noted.

EXHIBIT NO. 74.

Photograph No. 7.

VIEW OF THE COSTAL SURFACE OF RIGHT LUNG, SHOWING A SLIGHTLY CONGESTED CONDITION WITH A MODERATELY HIGH DEGREE OF SUB-PLEURAL ANTHRACOSIS.

The pleura is opaque over a large part and slightly cloudy over all the rest. The fissure between the superior and middle lobe is obscured by a thickened pleura and only part of the fissure between the superior and inferior lobe is visible. The pleura shows the effect of chronic pleuritis with adhesions to the visceral pleura which have not disfigured the contour of the lung. These adhesions have been very dense and represent either a repeated mild infection or a mild chronic infection to which good resistance has been offered.

EXHIBIT NO. 75.

Photograph No. 8.

VIEW OF THE INTERNAL SURFACE OF NO. 7 (RIGHT LUNG).

Above the center may be seen the section of the main bronchus above the pulmonary artery. Below and to the right of this artery is the opening of the pulmonary vein. The tissue spread out to the right is part of the areolar tissue of the mediastinum and the pericardium. This was slightly adherent to the lung, and a portion of the torn surface may be seen near the upper margin. The nodules seen near the center of the section are lymph nodules of normal size. Above the bronchus the large dark blue object is a markedly anthracotic superior bronchus lymph gland. The adhesions described under No. 7 may be seen to the left of the picture, and the thickened pleura is stretched out as a gray veil over the posterior surface to the left. The sub-pleural anthracosis is unusually marked and its profuseness is very apparent on the diaphragmatic surface.

EXHIBIT NO. 76.

Photograph No. 9.

SECTION OF BOTH LOBES OF TUBERCULOUS LUNG (LEFT) ON POSTERO-LATERAL-COSTAL SURFACE.

The upper half of the superior lobe shows irregular caseous infiltration, as indicated by the light colored areas, separated by partly functionating and slightly anthracotic lung tissue. The lower half of this lobe shows complete consolidation by caseous infiltrate, probably a late stage of caseous pneumonia. The process has not extended across the pleural septum to the lower lobe. In the lower

lobe vessels may be seen opened longitudinally, toward the extreme lower end, and on the side of the fewer blood vessels pale areas may be seen. These represents early tuberculosis areas. The varnish applied to this plate has not dried well; therefore, cracks are noticeable on the starched film.

EXHIBIT NO. 77.

Photograph No. 10.

VIEW OF TUBERCULOUS LEFT LUNG, SHOWING SECTION THROUGH BOTH LOBES.

In the center, open blood vessels are noted and around them are enlarged anthracotic glands. These are not opened but appear caseous. In the upper lobe are many areas of disseminated caseous infiltration, and one small cavity is found above but slightly to the left of the middle of the upper lobe. The lower part of the section shows moderate hypostatic congestion. The pleural covering intact is noted below and to the right. The other section shows an opened spleen with caseous masses of various sizes.

EXHIBIT NO. 78.

Photograph No. 11.

ANOTHER VIEW OF PHOTOGRAPH NO. 10.

EXHIBIT NO. 79.

Photograph No. 12.

SECTION OF RIGHT LUNG SHOWING CAVITY AND INFECTED GLANDS AROUND HILUS OF LUNG.

The cavity is to the left and a grape-like arrangement of the caseous nodules is noted in the vicinity of the cavity. The latter shows projecting teats of tissue which originally stretched across it but have been divided by the process of ulceration.

EXHIBIT NO. 80.

CHART SHOWING INFECTION WITH TUBERCULOSIS OF THE SUCCESSIVE OCCUPANTS OF AN ISOLATED FARM HOUSE.

This chart shows graphically the possibilities of house infection where carelessness, indifference or ignorance exists on the part of tuberculosis sufferers, and when neglect of disinfection makes evil results possible to a remote degree. Tuberculosis under such conditions becomes a wide spread menace not confined to the overcrowded tenements of large cities.

The above house is located in Cumberland county. The following is a history of another farm-house in Juniata county.

History Previous to 1898.—No definite history of tuberculosis although there is reported one suspicious case, a negro who underwent amputation of one leg because of "some disease."

1900-1902.—Family of J. E. moved into house 1898. Husband's family history, negative. Wife's history, doubtful. First case Mrs. J. E. died 1902. During 1902 there developed tuberculosis in the husband, one son and two daughters. A short time after moving from the house one other daughter developed tuberculosis and at the present time one additional daughter is under observation, there being strong evidence of early infection.

Of the J. E. family within six years after moving into the house six members died of tuberculosis and two are still living, both infected.

1902-1904.—T. moved into house 1902. Family history both Mr. and Mrs. T. negative. 1903 one son, one daughter and Mrs. T. developed tuberculosis and died. One son and one daughter have developed the disease and are now under treatment.

A Mrs. M. not connected with this family having a good family history was a frequent visitor during the occupancy of the house, and in 1904 contracted tuberculosis.

1904-1906.—Family of R. L. occupied the house. Family history negative. In 1905 one son contracted tuberculosis and died. During the occupancy of the house three other members of the family developed tuberculosis.

Since leaving the house one additional member has been in poor health and is now under observation, numerous signs pointing to infection.

1906-1908.—Since 1906 the house has been occupied by a family of negroes who are all apparently in healthy condition. The father of the present occupant is said to have lived in the house previous to its occupancy by the man whose leg was amputated for the suspicious disease.

Physical Conditions of House—Inspection of the house shows it to be built upon the southwest shore of the Juniata far separated from other buildings, the ground falling away on all sides. In fact the location might be pronounced excellent. The house is built of wood and is well supplied with windows on three sides, the fourth side or northwest side, having but one window.

EXHIBIT NO. 85.

MODEL DISPENSARY.

This room as fitted up is designed to show the general equipment and furnishing of the dispensaries for tuberculosis which the State Department of Health has located in each county.

SUB-DIVISION OF SPECIAL MEDICAL INSPECTION.

John A. Bouse, M. D., Special Medical Inspector.

During the earlier months of the year this sub-division was engaged in the organization of Boards of Health in first class townships of the counties of Allegheny, Beaver, Delaware, Lackawanna, Lebanon, Lehigh, Luzerne, Montgomery and Northumberland. We succeeded in securing organized Boards of Health in all the first class townships in Allegheny county except Harrison and Reserve. These townships are now under way of organization.

North Versailles township of Allegheny county has been recently reported a first class township and now has an organized Board of Health. The whole number of first class townships in the State is 31.

Foster and Hazle townships, two second class townships of Luzerne county, organized their School Boards into Boards of Health under the Act of April 7, 1899, and are now taking charge of the sanitary affairs in these townships.

Special reports from all of the townships above mentioned are on file in this office. The reports received on communicable diseases from the secretaries of the various Boards are usually prompt.

Reports rendered during the year show the following Boards of Health organized, by counties:

ADAMS.
- McSherrystown.
- York Springs.

ALLEGHENY.
- Brackenridge.
- Clairton.
- Glen Osborne.
- Rankin.
- Spring Garden.
- West Elizabeth.
- West View.

ARMSTRONG.
- Applewald.
- Johnetta.
- Manorville.
- Queenstown.
- Rural Valley.

BEAVER.
- Glasgow.
- Darlington.
- East Rochester.
- Georgetown.
- Midland.

BEDFORD.
- Coaldale.
- Hopewell.
- Hyndman.
- Mann's Choice.

- Adamsburg.
- Arona.
- Cokeville.
- Delmont.
- Greensburg.
- Seward.
- Smithton.

WAYNE.
- Honesdale.
- Hawley.

In concluding this report I wish to add that our correspondence has been of considerable moment, as we have taken up the various requirements and regulations of this Department regarding the reporting of communicable diseases the proper quarantine period, and also the matter of room and house disinfection. We have found our Circular No. 6 to be an invaluable aid to borough Boards of Health, and to be highly appreciated by the same.

We are still receiving complaints from Boards of Health with regard to physicians who fail to report communicable diseases.

The greatest difficulty encountered is that many Borough Councils refuse adequate financial support to Boards of Health. They are unable to furnish the necessary forms for reporting communicable diseases to the Secretary, as well as the other necessary literature. Councils do not seem to understand the provisions of the Act of May 11, 1893, or carelessly disregard it. With proper financial support many Boards of Health would become active. Regarding this particular feature we would suggest that a circular letter be issued by this Department citing the law to Councils and urging a strict compliance therewith.

The following is a resume of information obtained by correspondence with the authorities of boroughs arranged by counties:

ADAMS COUNTY.

Arendtsville. Population 393. Recent information to the effect that a Board of Health has been appointed but not organized.

Biglerville. Population 200. No response to our letters.

New Oxford. Population 663. Recent advice that organization will be perfected during the present month.

ALLEGHENY COUNTY.

Breckenridge. Advice to the effect that appointments have been made but no organization effected. Have visited this place but could get no satisfactory assurance of prompt organization.

North Braddock. Under process of organization at present.

Osbourne. Population 362. Have visited Osbourne and succeeded in organizing a Board which immediately resigned owing to some apparent pique over sewage disposal plans.

ARMSTRONG COUNTY.

South Bethlehem. Population 183. We have failed to receive any reply to correspondence with reference to organization of a Board of Health.

BEAVER COUNTY.

Darlington. Population 270. More recent advice to the effect that a Board of Health has been appointed but not organized. We have written for the name and address of the Secretary, but no reply.

Frankfort Springs. Population 198. No organization.

Georgetown. Population 271. Advised that Board is appointed but have up to the present date failed to furnish the name of the Secretary.

Hookstown. Population 259. No reply to our communications.

BEDFORD COUNTY.

Mann's Choice. Population 312. Board resigned. Letter from Secretary advising of his resignation. This was followed by letter to President of Council requesting him to furnish the name of the new Secretary. No reply.

New Paris, Population, ... 205
St. Clairsville, Population, ... 102
Pleasantville, Population, ...
Woodbury, Population, ... 226

Recently visited Bedford county and interviewed the various officials who promised to proceed at once with the organization of Board of Health. These towns are so small and are under such poor municipal government that I question very much whether an efficient Board of Health could be organized therein.

BERKS COUNTY.

Bechtlesville. Population 361. Letter from Borough Solicitor stating that they could not obtain any men to serve on a Board of Health.

Centreport. Population 141. No Board yet organized, but letter asking for information concerning manner of organizing received and package was sent.

BLAIR COUNTY.

Newry. Made a recent visit to this Borough and had a very satisfactory interview with the President of the Borough Council who said he would proceed with the appointment at once and that in the early part of this month, would, if possible, complete the organization.

BRADFORD COUNTY.

Wyalusing. Population 525. Report Board appointed and will advise this Department as soon as organized of the name of Secretary.

BUTLER COUNTY.

Connoquenessing, Population,	343
Fairview, Population,	235
Karns City, Population,	265
Petrolia, Population,	350
Portersville, Population,	195
West Liberty, Population,	90

The above mentioned towns have all been notified of their duty regarding the organization of Boards of Health but in every instance we have failed to receive any response.

Zelienople. Population 963. Board has been appointed but name of Secretary is not reported.

CAMBRIA COUNTY.

Chest Springs is the only borough in this county not organized. All the Boroughs in this County except this particular one, have responded to all requests and a number of these boroughs have recently organized. Chest Springs reports Board appointed but we cannot obtain the name of the Secretary.

CARBON COUNTY.

Parryville. Population 723. Reports Board appointed but not organized.

Weissport. Population 445. Find it hard to get any one to serve on the Board of Health.

CENTRE COUNTY.

Centre Hall. Population 537. No reply to our communications.

Snow Shoe. Population 600. This Borough reports a Board appointed, but not yet organized.

CHESTER COUNTY.

Hopewell. Population 182. No reply to communications.

CLARION COUNTY.

Strattonville. Population 602. No reply to communications.

CLEARFIELD COUNTY.

Brisbin. Population 666. Unable to secure the services of any as members of the Board of Health.

Burnside. Population 647. Unable to get any one to serve.

Grampian. Population 606. Visited this Borough recently. Had a conference with a number of the gentlemen of the borough, including the chief burgess and physicians, who will take the matter up immediately and proceed with the appointment of a Board of Health.

Newburg. Population 314. No reply to our communications.

Wallaceton. Population 289. This Department is advised that the Council are acting as a Board of Health. We wrote them that this was illegal.

COLUMBIA COUNTY.

Orangeville. Population 439. Impossible to get men to serve on Board.

CRAWFORD COUNTY.

Centreville. Population 260. Letter from President of Council advising of his inability to procure members to serve on Board.

Hydetown. Population 337. Unable to get men to serve on Board.

Townville. Population 327. Board appointed and this Department wrote to each individual member urging their prompt organization. Up to date no reply.

This process has been observed with reference to a number of boroughs reporting appointments.

Uniontown. Population 359. No answer to our communications. During my early connection with this Department I visited this town and received promise of this organization but nothing has resulted.

ERIE COUNTY.

Platea. Population 250. No reply to our communications.

Waterford. Population 1,457. Reports a Board of Health appointed, giving the names thereof to whom we wrote urging the organization and asking for the name of the Secretary.

FAYETTE COUNTY.

Fayette City. Population 1,995. No reply to our communications.

Smithfield. Population 525. No reply to our communications..

Vanderbilt. Population 1,800. Letter giving names of men appointed to whom we wrote. No reply.

HUNTINGDON COUNTY.

Cassville. Population 168. Have been in recent communication with this borough and awaiting reply.

Markelsburg. Population 260. No reply to our communications.

INDIANA COUNTY.

Mechanicsburg. Population 161. Board appointed but not organized.

JEFFERSON COUNTY.

Worthville. Population 154. Letter from President of Council asking for information and instructions which were immediately furnished with reference to organization of Board of Health.

JUNIATA COUNTY.

Port Royal. Population 546. Visited Port Royal and had a conference with the Burgess, or President of Council, who assured me that they would organize a Board of Health promptly.

Thompsontown. Population 273. Visited this place and had a conference with the President of Council, who promised prompt organization.

LACKAWANNA COUNTY.

Elmhurst. Population 444. No reply to communications.

Glenburn, Population, ... 307

Gouldsboro, Population, ... 93

This Department advised of the impossibility to get men to serve on account of the small population.

LANCASTER COUNTY.

Terre Hill. Population 891. Letter from President of Council stating that he would take this matter up with Council and a latter report to the effect that the organization is under way.

LAWRENCE COUNTY.

Enon Valley. Population 395. Board organized but up to date we have failed to receive name of Secretary .

Volant. Population 120. Board appointed December 15th but not organized.

LEBANON COUNTY.

Jonestown. Population 571. Board not organized.

LUZERNE COUNTY.

Dallas. Population 543. Report Board appointed but we are unable to ascertain the name of the Secretary.

New Columbia. Population 202. No reply to our communications.

Warrior Run. Population 965. Board of Health resigned for the reason that Council refused any appropriation or to support them in any way. We have taken this matter up with the President of Council.

Yates. Population 443. No reply to our communications.

MERCER COUNTY.

Clarksville. Population 220. This Department notified that Board has been appointed, have written for name of Secretary.

Sheakleyville. Population 164. This Department furnished with names of men appointed on Board of Health. Wrote urging a prompt organization, but no reply.

MONROE COUNTY.

Stroudsburg. Population 3,654. Secretary resigned. Have not received name of successor.

MONTGOMERY COUNTY.

East Greenville. Population 894. No reply to our communications.

Green Lane. Population 272. Board appointed but failed to organize. Wrote to President of Council asking him to proceed to appoint a new Board.

MONTOUR COUNTY.

Washingtonville. Population 212. Letter advising the Department of inability to secure men to serve on Board.

PERRY COUNTY.

New Buffalo. Population 171. No reply to our communications.

POTTER COUNTY.

Lewisville. Population 618. Under process of organization.

SCHUYLKILL COUNTY.

Girardville. Population 1,165. This borough persistently refuses to organize, or pay any attention to our communications. We have received complaints concerning communicable diseases.

Middleport. Population 540. Letter from President of Council stating that Board was appointed October 5th. Has not yet reported organization.

Port Clinton. Population 478. No reply to our communications.

SOMERSET COUNTY.

Jennertown. Population 96. No reply to our communications.

Paint.

Somerfield. Population 178. The above boroughs are all of such small population that it seems impossible to obtain the services of any one as members of the Board of Health.

SULLIVAN COUNTY.

LaPorte. Population 442. No reply to our communications.

SUSQUEHANNA COUNTY.

Little Meadows. Population 213. Information to the effect that is is impossible to organize a Board of Health owing to the fact that it is impossible to get men to serve and that the town contains no resident physician.

This is also true of many other small boroughs in the Commonwealth.

TIOGA COUNTY.

Lawrenceville. Population 486. No reply to communications.

VENANGO COUNTY.

Utica. Population 268. No reply to communications.

WASHINGTON COUNTY.

Beallsville. Population 368. Had a personal interview with the President of Council who promised to appoint a Board of Health which I think he endeavored to do. We have received letter to the fact that the Board has refused to organize.

Long Branch, Population, ... 270
Speers, Population, ... 369
Twilight, Population, ... 136

These are very small municipalities with regard to population.

Houston. Reports a Board appointed, advises that they will proceed with organization immediately.

Midway. Population ——. Letter from President of Council stating that they could not organize a Board in this borough because of having no resident physician. We instructed them to proceed with organization leaving the place of physician vacant until such time as they could secure the services of a physician.

West Middletown. Population 244. School directors organized and acting as Board of Health.

WAYNE COUNTY.

Bethany. Population 130. Board appointed but not organized.

Prompton. Population 258. Letter stating that there was not enough people from which to get a Board of Health.

WESTMORELAND COUNTY.

Donegal. Population 157. Too small a population from which to secure a Board of Health.

East Vandergrift. Population 2,076. Visited this borough and secured the promise of organization. Up to this time no reply.

Madison. Population 464. Letter stating inability to secure men to serve.

New Alexandria. Population 364. Board appointed but failed to organize.

New Florence. Population 800. No reply to communications.

Youngstown. Population 771. No reply to communications.

YORK COUNTY.

East Prospect. Population 292. Visited this place. Had conference with borough officials but they have failed to organize.

Fawn Grove. Population 202. No Board.

Franklin. Population 374. Unable to secure a Board.

Jefferson. Town Council illegally acting as Board of Health.

Loganville. Population 343. Visited this place and conferred with the Chief Burgess but cannot effect an organization.

Wellsville. Population 296. Unable to get men to serve on Board.

New Salem. Population 241. Unable to procure proper persons to serve on Board.

THE DIVISION OF SANITARY ENGINEERING.

F. HERBERT SNOW, C. E., *Chief Engineer.*

THE DIVISION OF SANITARY ENGINEERING.

CONTENTS.

DIVISION OF ENGINEERING.

The following is a detailed statement of the operations of the Engineering Division of the State Department of Health to the end of the year 1908, being the third annual report of the Division made since the creation of the Department of Health under Act No. 281, approved April 27, 1905.

I. ORGANIZATION AND ADMINISTRATION.

OFFICE AND OFFICE FORCE.

Mr. F. Herbert Snow has continued throughout the year to discharge the duties of his position as Chief of the Engineering Division of the Department.

The offices of the Division are on the ground floor front, north corridor, and on the fifth floor, south corridor, of the Capitol, and are those occupied by the Division during the preceding year.

Six subdivisions of the organization have been created in the administration of the work put upon the office, namely, that of general office work; that pertaining to water works and sewerage applications that relating to special investigations; that relating to design and construction; that of map making and, finally, that of sanitary regulation.

There have been employed in the office nine stenographers and five clerks.

ASSISTANT ENGINEERS.

Mr. Walter S. Hanna has continued to discharge the duties of Assistant Engineer in direct charge of the general office work. Messrs. Ira L. Miller and Horace P. Rees were appointed in October and November, respectively, and were assigned to aid Mr. Hanna.

Mr. Chester F. Drake was appointed in February to the position of Assistant Engineer in charge of the investigations of water works and sewerage applications. Mr. Drake resigned later to accept the office of Superintendent-in-charge of the municipal water filter plant of the city of Pittsburg.

Mr. William H. Ennis remained at the Mont Alto State Sanatorium as Resident Engineer on construction work until July, when he was transferred to the office at Harrisburg as an Assistant Engineer on water works and sewerage investigations.

Mr. Howard E. Moses was appointed in June and served as an Assistant Engineer on Water works and sewerage investigations. The greater part of his time has been devoted to special sanitary investigations in Allegheny county.

Mr. Paul Hooker received his appointment in September as assistant engineer on water works and sewerage investigations. He has devoted much time to a special study and report on the Allegheny river drainage basin conditions with respect to water supply and sewerage.

Mr. Moylan E. Shaughnessy was transferred from the field inspecting force to the water works and sewerage investigating force. Besides making engineering investigations along these lines, he has made numerous sanitary inspections and compiled maps for the field inspecting force in Allegheny county.

Mr. Charles H. Cummings has continued as principal assistant engineer in charge of special engineering investigations.

Mr. Ralph E. Irwin, who was employed during the summer months of the previous year, received a permanent appointment in June as assistant engineer on special investigations.

Thomas Fleming, Jr., continued as principal assistant engineer in charge of designs and construction.

Under the personal supervision of Mr. Ennis at Mont Alto was a surveying party, composed of Mr. Chester A. Eckbert, transitman; Mr. Frank L. Gardner, engineer and inspector; and Mr. Ivan M. Glace, rodman. In the office, John M. Mahon, Jr., and Mr. Harry A. Otto, engineering draftsmen, were employed on the design of various structures. Mr. Glace was transferred from field work to design work in January, and later was assigned to the drafting force. Mr. Eckbert was transferred to the office force in February, and later to the drafting force. Mr. Charles R. Forbes was transferred from the drafting force to design work in the office, and in April was sent to Mont Alto as a transitman.

Mr. Albert H. Beard was appointed to the position of assistant engineer in July. He at once reported at Mont Alto and assumed the position of resident engineer on construction.

Mr. Coleman B. Mark was transferred in August from the field inspecting force to the construction force at Mont Alto. He had had previous experience as inspector of construction work.

Mr. James L. W. Gibbs has continued as chief draftsman in charge of map making. The following men were employed under him to make maps or tracings: John W. German, Jr., F. Marion Sourbeer, Charles R. Forbes, Edgar R. Barnes, Chester A. Eckbert, Ivan M. Glace, Max H. Matthes and George Williams. Messrs. Eckbert, Glace and Barnes has previously been on the construction work at Mont Alto; Mr. Matthes, of the field inspecting force, and Mr. Williams spent some time in assembling maps and charts for use in the Pennsylvania Exhibit of the International Tuberculosis Congress, held at Washington, D. C. The office force has, therefore, varied from five men, at the commencement of the year, to eight at the end.

Mr. Moses K. Ely, the chief sanitary inspector, has been in charge of bureau work incident to the supervision of all field officer's work.

These assistants have comprised the permanent force, but at intervals during the year eleven other engineers, residents of the State, were called upon to render assistance of a specific character. These names are presented in alphabetical order:

L. E. Chapin,	Pittsburg.
Harvey Linton,	Altoona.
Chas. F. Mebus,	Philadelphia.
Marshall R. Pugh,	Philadelphia.
Mason D. Pratt,	Harrisburg.
F. H. Shaw,	Lancaster.
H. S. Smith,	Wilkes-Barre.
John H. Strauch,	Pottsville.
D. F. A. Wheelock,	Warren.
Elton D. Walker,	State College.
George F. Hodkinson,	Philadelphia.

Mr. Chapin made an examination and report relative to sewerage and sewage disposal of New Wilmington.

Mr. Linton made investigations of the sewerage system at Bellefonte, the sewerage system in Farmaugh township, Juniata county, and the water-works system of Juniata borough. He also made a special investigation of the watershed of the Altoona City water-works.

Mr. Mebus made investigations and reported on the sewerage systems of the city of Chester, city of Wilkes-Barre, borough of Ridley Park and the borough of Upland. Investigations and report on the proposed sewerage disposal plants of the House of Refuge, Girls Department, at Darlington, and of the Pennsylvania School for Feeble-Minded Children at Elwyn. He made a report on the operation of the sewage disposal plant at Wayne and one on the operation of the sewage disposal plant at Dermady Cottage Sanatorium near Morton, Delaware county. He also made an examination and report on the location of a proposed sewage disposal plant at New Castle, and with respect to sanitary conditions near Ambler.

Mr. Pugh examined and reported on sewage pollution and nuisance near Narberth, on plans and proposed locations of a sewage disposal plant for the Williamson Trade School in Delaware county, and on the water-works systems in Emaus borough.

Mr. Pratt made investigations and reported on sewerage and water-works in the borough of Mt. Union, water-works belonging to to the Blossburg Water Company, and on a sewerage system at Eaglesmere.

Mr. Shaw made sewerage investigations at Corry and water-works investigations at Palmyra, Parkesburg, Mountville and Huntingdon.

Mr. Smith reported investigations on sewerage at Winton borough and Shenandoah borough; also on the water-works system at the latter place.

Mr. Strauch made a special investigation of the water-works system at Schuylkill Haven and at the State Hospital at Minersville.

Major Wheelock made water-works investigations at Austin and at Emlenton, of the Winburne Water Company, Trotter Water Company, Beaver Valley Water Company and Anthracite Water Company systems. He made sewerage investigations at the Columbus Tannery, near Corry, of the Erie Improvement Company in Mill Creek township, Erie county, at Clintonville and Tyrone. Both water-works systems and sewerage systems were investigated and reported on by him in the following municipalities: Wellsboro, Beaver Falls, Erie City, Mercer, College Hill, East Vale, Patterson Heights, New Brighton, Rochester, Freedom, Conway, Fairchance, Fallston, West Bridgewater, James City, Union City, Punxsutawney, Reno, Mars, West End and Parker City.

Professor Walker reported on the sewerage systems of Sharpsville, city of McKeesport, Allentown, Danville and State College borough.

See Royersford and Spring City for Mr. Hodkinson's work.

FIELD OFFICERS.

Besides the sanitary inspectors in the employment of the Department at the beginning of the year, thirty-two additional sanitary inspectors have been appointed by the Commissioner of Health. The

name, place of residence and date of appointment of each is given below:

Charles H. Glenn,	Philadelphia,	March, 1908.
Stuart H. Heist,	Harrisburg,	April, 1908.
Timothy Whelan,	Clifton Heights,	April, 1908.
James A. Walker,	Philadelphia,	April, 1908.
Roland B. Styer,	Lancaster,	May, 1908.
J. B. Baumgardner,	Chambersburg,	May, 1908.
John W. Eisenhart,	York,	May, 1908.
Richard Bayard,	Dauphin,	June, 1908.
Moylan E. Shaughnessy,	Lewistown,	June, 1908.
Howard B. Moore,	Harrisburg,	June, 1908.
J. A. McCleary,	Altoona,	August, 1908.
Robt. S. Hansbury,	Philadelphia,	August, 1908.
Harry E. Magee,	Philadelphia,	August, 1908.
J. D. Marshall,	New Castle,	August, 1908.
William Ellis,	Phoenixville,	August, 1908.
Coleman B. Mark,	Harrisburg,	August, 1908.
Frank H. Lanard,	Philadelphia,	August, 1908.
J. F. McElwee,	Bedford,	August, 1908.
Fred Fletcher,	Columbia,	August, 1908.
J. M. Silliman,	Tamaqua,	September, 1908.
D. M. Irwin,	Greensburg,	September, 1908.
Harry A. Miller,	Lebanon,	September, 1908.
William C. Riddle,	Lancaster,	September, 1908.
William H. Bisbing,	Norristown,	October, 1908.
Edward C. Mitchell,	Bethlehem,	October, 1908.
Joseph S. Couch,	Oil City,	October, 1908.
John E. Perry,	Harrisburg,	October, 1908.
Ira L. Miller,	Harrisburg,	October, 1908.
E. H. Everett,	New Haven,	October, 1908.
Jesse E. Dale,	Patton,	November, 1908.
William P. Miller,	Pittsburg,	November, 1908.*
Thos. W. Templeton,	Plymouth,	November, 1908.

Deputy field officers, so called, because while being in the employ of a private corporation, they are deputized to represent the Commissioner of Health in inspecting the sanitary condition of property and to report results to him, were appointed in four instances prior to 1907. During the current year four additional appointments were made. The name, residence of each and date of appointment is given below:

H. N. Blunt,	Palmerton,	June, 1906.
L. E. Agnew,	Alderson, Harveys Lake,	June, 1906.
Wm. G. Edmunds,	Nanticoke,	June, 1906.
Howard Seabold,	Catasauqua,	November, 1906.
E. M. Stack,	Scranton,	April, 1908.
John Brown,	Scranton,	April, 1908.
Emil Amann,	Warren,	May, 1908.
David Decker,	Ridgway,	June, 1908.

REGULAR FORCE.

On December 31, 1908, the regularly employed force under my direction—the names being given alphabetically—was as follows:

CLERKS.

Bayard C. Dickinson,	Chief Clerk—Local Health Officer Work.
Richard F. Einstein,	Clerk of Field Inspection Work.
Howard M. Haines,	Clerk of Field Inspection Work.
Ellen Johnston,	Clerk of Files.
Daniel V. Ness,	Chief Clerk in Charge Nuisance Complaints.

*Reappointed.

STENOGRAPHERS.

M. Irene Cuenot.
M. Louise Eckels.
Elizabeth R. Fleisher.
Jane Gilbert.
Leola R. Hannah.
M. Ethel Hurst.
Clara V. Mahaney.
Mary E. Russell.
Mary K. Sourbeer.

ASSISTANT ENGINEERS.

Albert H. Beard, ... Resident Engineer, Mont Alto.
Charles H. Cummings, ... Principal Assistant in Charge Special Investigations.
William H. Ennis, ... General Investigations.
Thomas Fleming, Jr., ... Principal Assistant in Charge Design and Construction.
Charles R. Forbes, ... Chief—Surveying Party.
Frank L. Gardner, ... Engineer Inspector.
Walter S. Hanna, ... Principal Assistant in Charge General Office Work.
Paul Hooker, ... Principal Assistant in Charge Water and Sewerage Investigations.
Ralph E. Irwin, ... Chemical and Bacteriological Examination.
John M. Mahon, Jr., ... Construction Design.
Coleman B. Mark, ... Construction Inspection.
Ira L. Miller, ... General Office Work.
Howard E. Moses, ... General Investigations.
Harry A. Otto, ... Construction Design.
Horace P. Rees, ... General Office Work.
Moylan E. Shaughnessy, .. General Investigations.

DRAFTSMEN AND TRACERS.

Edgar R. Barnes.
Chester A. Eckbert.
John W. German, Jr.
James L. W. Gibbs—Chief Draftsman.
Ivan M. Glace.
Max H. Matthes.
F. Marion Sourbeer.
George Williams.

SANITARY INSPECTORS.

Henry Andrews, ... Field Officer.
Richard Bayard, ... Field Officer.
John B. Baumgardner, ... Field Officer.
James M. Clark, ... Field Officer-in-Charge.
David M. Coleman, ... Field Officer-in-Charge.
John J. Considine, ... Field Officer-in-Charge.
William K. Claypool, ... Field Officer.
Joseph S. Couch, ... Field Officer.
Jesse E. Dale, ... Field Officer.
John W. Downes, ... Field Officer.
Moses K. Ely, ... Chief Sanitary Inspector and Bureau Officer.
John W. Eisenhart, ... Field Officer.
E. H. Everett, ... Field Officer.
Fred Fletcher, ... Field Officer.
Morris Z. Frederick, ... Field Officer.
Charles H. Glenn, ... Field Officer.
Stuart H. Heist, ... Special Field Officer.
Warren S. Hood, ... Special Field Officer.
Robt. S. Hansbury, ... Field Officer.
D. M. Irwin, ... Field Officer.
Harry S. Kauffman, ... Field Officer.
Frank H. Lanard, ... Field Officer.
Howard B. Moore, ... Field Officer-in-Charge.
Charles T. Maclay, ... Field Officer.
William P. Miller, ... Field Officer.
Ira L. Miller, ... Field Officer.
J. D. Marshall, ... Field Officer.
Edward C. Mitchell, ... Field Officer.
Harry E. Magee, ... Field Officer.
J. A. McCleary, ... Field Officer.
John B. Nightingale, ... Field Officer-in-Charge.
Thomas R. Nicholson, ... Field Officer.

SANITARY INSPECTORS—Continued.

Otto F. Nickel, ... Field Officer.
John W. Pinkham, ... Field Officer.
John E. Perry, ... Field Officer.
Wilson W. Ritter, ... Special Field Officer.
William C. Riddle, ... Field Officer.
W. W. Reno, ... Field Officer.
Charles H. Spelker, ... Field Officer.
J. H. Silliman, ... Field Officer.
Roy Souder, ... Field Officer.
Roland B. Styer, ... Field Officer.
William R. Teats, ... Field Officer-in-Charge.
Thos. W. Templeton, ... Field Officer.
Timothy Whelan, ... Field Officer.
Daniel Zellers, ... Special Field Officer.
Ira F. Zeigler, ... Special Field Officer.

Mr. E. T. Edwards, City Health Officer for Johnstown, has continued to represent the Department as a special sanitary inspector in the immediate territory beyond the jurisdiction of that city.

LOCAL HEALTH OFFICERS.

To better administer the work of the Department throughout the 1,519 second-class townships of the Commonwealth, wherein reside over two and one-third millions of people, entirely without sanitary protection such as is afforded by the Boards of Health of first-class townships and the boroughs of Pennsylvania, the Commissioner of Health had the State—66 counties, excluding Philadelphia—divided into sanitary districts, totalling 733, for each of which he appointed a resident agent.

In so far as possible and practicable, township boundaries were followed. Usually a district comprises two or more townships, including the boroughs and cities therein. For instance, Logan township, Blair county, including within it Altoona City and Juniata borough, comprises a district. The city of Pittsburg proper is a district by itself, and so is Allegheny City.

The resident sanitary agent of the Commissioner of Health, in so far as his duties relate to the Medical Division of the Department, is confined to the territory wholly without the borough, city and first-class township, because these municipalities are required by law to have their own organized boards of health; but everywhere within his district, regardless of the municipal boundaries, the resident sanitary agent is expected to investigate stream pollutions, water-works and sewers, to render assistance to field officers, and to report to the chief of the Engineering Division.

The work performed for the Engineering Division of the Department appears elsewhere herein.

OFFICE WORK.

The general office work necessary to administer the operations of the Division, including general correspondence, recording corporation reports and plans required by law to be filed in the office of the Department, or in compliance with decrees of the Commissioner, attention to petitions and complaints, the issuing of orders for the abatement of nuisances and menaces, and the preparation of plans

of watersheds for the use of sanitary inspectors in the field, comprises the subjects treated of in this part of the report under the head of office work. More or less office work is performed in connection with the sub-divisions of the organization and it is mentioned elsewhere.

CORPORATION REPORTS.

Under provisions of Law No. 182 of the Acts of the Assembly of Pennsylvania, approved April 22, 1905, entitled "An Act to Preserve the Purity of the Waters of the State for the Protection of the Public Health," it is the duty of every municipal corporation, private corporation, company and individual supplying or authorized to supply water to the public within the State to file with the Commissioner of Health a certified copy of the plans and surveys of the water-works, with a description of the source from which the supply of water is derived.

Under the provisions of the same law it is the duty of the public authorities having by law charge of the sewer system of every municipality of the State to file with the Commissioner of Health a report of such sewer systems, which shall comprise such facts and information as the Commissioner of Health may require.

One hundred and sixty-one reports were received. Thirty-three of them were from municipal corporations and 128 were from private corporations.

The municipal returns comprised 6 water supply reports and 27 sewerage reports.

The private corporation reports pertained to 124 water-works systems and 5 sewerage systems.

The Department has now on file information obtained in this formal way relative to water supply in 788 places, and relative to sewerage in 427 places.

RECORDED PLANS.

On December 31, 1908, there were 5,616 official plans registered in the Department, 2,017 having been added during the year, and of the grand total, 2,576 accompanied water-works and sewerage reports, of which 779 were added during the year; 2,358 accompanied water-works and sewerage applications, of which 766 were added during the year; and 472 were of a miscellaneous character, including some of the office working maps and those used in engineering and inspection work.

PETITIONS AND COMPLAINTS.

The Commissioner of Health, in addition to the powers conferred by the new law, has all the powers conferred, and must perform all the duties heretofore imposed by law upon the former State Board of Health, or any member, committee or officer thereof, including the secretary. The work of supervising the general interests of the health and lives of the citizens of the Commonwealth has been done in part in answer to petitions and complaints, and requests for advice. The Commissioner's instructions to give prompt attention to petitions, complaints and requests have been complied with in so far as the Department force made possible.

Hundreds of communications relative to stream pollutions by sewage, or by industrial waste, or with respect to unsanitary conditions, inferior water supply or ice supply, and respecting sewers, sewage disposal, water supply and general sanitation, have received attention.

Four hundred and sixty-one complaints and petitions have been acted upon during the year. Three hundred and eighty of these cases have been satisfactorily settled.

Thirty-one requests for advice relative to water supply, sewerage, garbage disposal, drainage of stagnant water, disposal of creamery and industrial wastes, and location and construction of cesspools have been answered.

Common nuisances located within the territory of a municipality having an organized board of health, and made the subject of complaint to the Commissioner of Health, have been referred by the Department to such local boards. There have been one hundred and seventy-six references of this kind during the year, as follows:

Stream Pollution. Avondale, Ashley, Bath, Chester, Hazleton, Juniata, LaPlume, LeRaysville, Lincoln Place, North East (2 cases), Patton, Tremont, Troy, West Conshohocken and West Newton.

Sewage in Street Gutters. Blairsville, Edenburg, Emporium, Hamburg, Houtzdale, Knoxville, Lebanon, Littlestown, McKeesport, Mt. Penn, Mt. Pleasant (2), New Bethlehem, Penbrook, Petersburg, Rimersburg and Smethport.

Sewer Outlet.. Blossburg, Chartiers township, Allegheny county, and Mt. Carmel.

Defective Sewer. Apollo, Ashley, Carrolltown, Chester, Glenolden, Greensburg, Pittsburg, Punxsutawney, Royersford, Sewickley and Southwest Greensburg.

Open Sewer. Bedford, Bellevue, Benton, Blairsvile, Blakely, Brownsville, Chartiers township, Allegheny county, Danville, East Stroudsburg, Fayette City, Hoboken, Lebanon, Mill Hall, Mt. Joy, New Bethlehem and Pittsburg.

Unsanitary Premises. Apollo, Ardmore, Bethlehem, Chambersburg, Chester, Coatesville, Curwensville (2), Darby (2), Duboistown (2), Dunmore (2), Duquesne, East Mauch Chunk, Ellsworth, Emaus, Ephrata, Everett, Fernwood, Galeton, Greensburg, Harrisburg (2), Hawley, Highspire (2), Hoboken, Houtzdale, Kane, Kingston, Laceyville, Lancaster, Langhorne, Lebanon (3), Lewistown, Lock Haven, Logantown, Malvern (2), Middletown, Milton, Montour, Mt. Union, Narberth, Newburg, North East, Petersburg, Pitcairn, Pottsville, Punxsutawney, Ridley township, Delaware county, Shamokin (2), Shenandoah, Shippensburg, Siverly, South Fork, Susquehanna, Tower City, Tyrone, Uniondale, Verona, Versailles township, Allegheny county, Waynesburg, Wellsboro and Wyomissing.

Dumping Grounds. DuBois, Grove City, Harrisburg, Lancaster, Lower Merion township, Montgomery county, New Philadelphia, Vandergrift and Waterford.

Dead Animals. Mt. Union.

Slaughter Houses. Adamstown, Coalport, Delta, Jamestown, Jeannette, Johnstown, Loganville, Manchester, Red Lion and St. Marys.

Swamp Land and Stagnant Water. Apollo, Avoca, Chambersburg, Cherry Tree, Columbia, Hartstown, Hyndman, Juniata, Latrobe, Mt. Union, Narberth, Orrstown, Pittston and Williamsport.

Impure Water and Ice Supply. Ashley, Barnesboro, Creekside, Harmony, New Galilee, Punxsutawney, Schuylkill Haven and Tamaqua.

Night Soil. DuBois.

Reduction Works. Lancaster.

At the close of the year, of the 176 cases referred to local boards of health, all but 26 have been adjusted to the satisfaction of the complainants. The Department will follow the remaining cases to a conclusion.

Two hundred and fifty-four complaints and petitions were made the subject of special investigations and report by the Engineering Division. The localities were usually outside of boroughs and cities and in territories where the Department of Health has adequate jurisdiction. Fifty-four of these commanded the services of engineers, field inspectors and county medical officers, and two hundred commanded the services of the local health officers. Classified, these subjects were as follows:

Nuisances in streams by sewage and industrial wastes,	54
Impure water and ice supply,	22
Sewerage systems,	11
Defective drainage,	6
Garbage and night soil dumps,	18
Unsanitary premises,	66
Nuisances in street gutters by sewage,	32
Slaughter houses,	7
Reduction, fertilizer and glue works,	5
Dead animals,	17
Mine drainage,	..
Swamp land and stagnant water,	13
Sewage disposal plants,	3
	254

The localities of the cases investigated are shown in the following statement:

Nuisances in streams by sewage and industrial wastes. In Allegheny county, Carnegie; in Bedford county, Sulphur Springs; in Berks county, Boyertown, Spangsville and Perry township; in Bradford county, Stevensville and Wyalusing; in Bucks county, Ben Salem township; in Cambria county, Ebensburg and Laurel Run; in Cameron county, First Fork Creek; in Centre county, Spring Mills; in Clearfield county, DuBois and Sterling; in Clinton county, Grugan township; in Cumberland county, Shippensburg; in Delaware county, Darby Creek, Millbourne and Drexel Hall; in Erie county, Mill Creek; in Fulton county, McConnellsburg; in Indiana county, Glen Campbell; in Jefferson county, Vicksburg; in Lackawanna county, Scranton; in Lehigh county, Coopersburg; in Luzerne county, Trucksville and Sybertsville; in Mercer county, Wilmington township; in Monroe county, Saylorsburg; in Montgomery county, Bryn Mawr and Upper Hanover township; in Philadelphia county, Chestnut Hill; in Pike county, Milford; in Schuylkill county, Tremont and Lost Creek; in Susquehanna county, Heart Lake, Montrose, Springville and Kingsley; in Union county, Vicksburg; in Washington county, Houston and Washington; in Wayne county, Inglehart, Star-

rucca and Texas township; in Westmoreland county, Jeannette, Manor Penn township, Stauffer and West Newton; in Wyoming county, Mill City; in York county, Hanover and York.

Where the above places are not designated as townships, the places named are villages or suburbs of boroughs. Sometimes in the latter instances the inspections involved examinations within the coroprate territory of the municipality.

Impure water and ice supply. In Allegheny county, Pittsburg; in Beaver county, Beaver Falls; in Berks county, Cumru township; in Blair county, Juniata; in Bradford county, Wyalusing; in Butler county, Buffalo township; in Centre county, Boalsburg; in Chester county, Supplee; in Dauphin county, Susquehanna township; in Montgomery county, Limerick and Colmar; in Monroe county, Stroudsburg; in Northampton county, Easton; in Northumberland county, Seven Points; Perry county, Penn township; in Potter county, Austin; in Sullivan county, Bernice; in Tioga county, Mansfield; in Venango county, Cranberry township; in Washington county, Canonsburg and Washington; in Westmoreland county, Latrobe.

Sewerage Systems. In Allegheny county, Ben Avon, Carrick and Ross township; in Berks county, Virginsville; in Cambria county, Brownstone and Spring Hill; in Lycoming county, Vilas; in Montgomery county, Lansdale; in Northumberland county, Mt. Carmel; in Westmoreland county, Mt. Pleasant and New Kingstown.

Defective Drainage. In Armstrong county, Kelly Station; in Dauphin county, Swatara township; in Huntingdon county, Huntingdon; in Jefferson county, Punxsutawney; in Union county, Lewisburg; in Westmoreland county, Pleasant Unity.

Garbage and Night Soil Dumps. In Allegheny county, McKeesport and Pitcairn; in Armstrong county, Georgetown; in Berks county, Muhlenberg township and Reading; in Chester county, Anselma, Berwyn, Devon and Paoli; in Clearfield county, DuBois; in Franklin county, Chambersburg; in Lancaster county, Gap; in Lawrence county, Union township; in Lehigh county, Old Zionsville; in Monroe county, Pocono township; in Montgomery county, McKinley and Upper Gwynedd township; in Perry county, Duncannon.

Unsanitary Premises. In Allegheny county, Bellevue, Sandy Creek, Tarentum and Versailles township (3); in Armstrong county, Kiskiminetas township; in Berks county, Wernersville (2); in Bucks county, Lahaska, Trevose; in Cambria county, Patton and Stony Creek township; in Carbon county, Weissport; in Centre county, Walker township; in Chester county, Berwyn, East Fallowfield township (2), East Marlboro township, Strafford and Warwick; in Clarion county, Phillipston; in Clearfield county, DuBois, Madera and Tylersburg; in Clinton county, Loganton; in Cumberland county, West Fairview; in Dauphin county, Linglestown, Susquehanna township (3), Swatara township (2) and Wiconisco; in Delaware county, Primos and Upper Darby township; in Erie county, Union township and Wesleyville; in Fayette county, Perryopolis and Redstone township; in Huntingdon county, Walker township; in Indiana county, Blairsville; in Lehigh county, New Tripoli; in Luzerne county, Nanticoke; in Lycoming county, Slate Run; in McKean county, Derrick City; in Mifflin county, Milroy; in Monroe county, Saylorsburg; in

Montgomery county, Ardmore, Bryn Athyn and Bryn Mawr; in Northampton county, Mt. Bethel; in Northumberland county, Dewart, Johnson City and Shamokin; in Perry county, Duncannon; in Westmoreland county, Arone, East Vandergrift and Penn Station; in Schuylkill county, Sheppton and Sheridan; in Snyder county, Port Treverton; in Tioga county, Cowanesque; in Wyoming county, North Mehoopany; in York county, Hanover.

Nuisances in street gutters by sewage. In Allegheny county, Ross and Scott townships; in Cambria county, Johnstown; in Cameron county, Emporium; in Chester county, Berwyn (2), Devon, Treddyfrin township; in Clarion county, Clarion township; in Clinton county, Avis and Mill Hall; in Dauphin county, Paxtang, Susquehanna and Swatara townships; in Elk county, Kersey; in Lackawanna county, Elmhurst and Simpson; in Lancaster county, Leola; in Lawrence county, Oakland; in Luzerne county, Ashley; in McKean county, Ludlow; in Mifflin county, Belleville; in Montgomery county, Berwyn, Haverford, Pottstown, Upper Dublin township, Valley Forge and Willow Grove; in Schuylkill county, Sheppton and Wade; in Westmoreland county, Claridge; in York county, York.

Slaughter House. In Allegheny county, Union Station; in Berks county, Stouchburg; in Erie county, North East; in Greene county, Monongahela township; in Montgomery county, Zeiglersville; in Schuylkill county, Valley View; in York county, Springettsbury township.

Reduction, Fertilizer and Glue Works. In Berks county, Cumru township; in Cameron county, Emporium; in Lebanon county, Myerstown; in Montgomery county, Whitpan township; in York county, Penn township.

Dead Animals. In Berks county, Shillington and Wernersville; in Blair county, Isett; in Chester county, Berwyn; in Crawford county, Centerville and Sadsbury township; in Franklin county, Greene township, Mercersburg; in Indiana county, Buffington township; in Lancaster county, Florin; in Mercer county, Springfield township; in Northampton county, Lehigh township; in Northumberland county, Turbotville; in Susquehanna county, Harmony township and Little Meadows; in Westmoreland county, Claridge and Harrison City.

Swamp Land and Stagnant Water. In Berks county, Douglassville and Heidelburg township; in Cambria county, Stony Creek township; in Center county, Rush township; in Dauphin county, Susquehanna township; in Erie county, Edinboro; in Indiana county, Hortons; in Lackawanna county, Coyne (2) and Hanover township; in Luzerne county, Pittston; in Philadelphia county, Manayunk; in Wyoming county, Mill City.

Sewage Disposal and Disposal Plants. In Allegheny county, Etna; in Columbia county, Centralia; in Luzerne county, White Haven.

Some of the petitions came from local Boards of Health and borough authorities, and in these cases the investigations were in the towns.

ORDERS OF ABATEMENT.

To prevent causes of disease and mortality, so far as the same may be caused by public menaces and nuisances, more especially outside of municipalities on the watersheds of the State, the Commissioner

of Health has the power and authority to order such nuisances and menaces to be abated and removed. Upon examination made by any persons duly authorized by the Commissioner of Health so to do, information as to the facts is submitted to this office and subsequently an order to abate or remove may be issued. These orders are signed by the Commissioner and served by the field or local health officers. The abatements listed below were had by formal notification. Many hundred of properties have been put in sanitary condition on inspection and verbal request by the field or local health officer.

Eight thousand three hundred and forty written orders have been prepared for issuance during the year. Six thousand two hundred and thirty-four of them were issued as the direct result of investigations on watersheds by the division field officers, and all but fifty-three of the menaces were found existing on drainage areas feeding public water supplies. They are more fully reported elsewhere herein. The fifty-three written orders were of a miscellaneous character, reported, in a large majority of the cases, by the local health officers who served the notices. Many of the other notices were also served by the local health officers under the supervision of the Department's field officers.

DRAFTING.

The map-making force varied from five men during the fore part of the year to eight men at the latter part, except when assistant engineers and field officers may have temporarily engaged in the preparation of plans in connection with work to which they were specifically assigned.

During the year maps of twenty different counties were made, each showing townships, boroughs, cities, post-offices, villages, railroad, street-car lines and streams. They are to serve as a basis for general reference, and more particularly as a foundation for future map making of districts within the county. The uniform scale of these maps is three miles to one inch. A total of 585 enlarged township maps were made from smaller maps, and blue print copies thereof were supplied to field officers for inspection work.

In connection with and to facilitate the work of a sanitary survey of the sources of minor pollutions on the watersheds of Ithan Creek, Little Darby Creek, Perkiomen Creek, West Creek and the Shenango River, a map of each shed has been prepared and copies thereof have been supplied to officers in charge of field work in these districts.

Special sanitary inspections of the boroughs and townships in Allegheny county necessitated the compiling of the proper maps to assist the inspectors in this work. Two men were sent to Pittsburg to make tracings of townships, borough and village maps from the authorized county atlas in the county court house. Fourteen township maps and thirty-two borough and village maps were prepared in this way.

For the International Tuberculosis Exhibit at Washington the Department prepared elaborate maps and charts to demonstrate the different methods and ways of treating patients afflicted with tuberculosis. Statistical charts were prepared. For this purpose three maps of Pennsylvania were made, one showing the death rate from tuberculosis per 100,000 inhabitants for each county, and other data of a similar nature; another showing the division of the State into

733 sanitary districts, and the last one showing the location of dispensaries for the free treatment of tuberculosis in each of the 67 counties. Ten charts were prepared, which show the following: The infection of tuberculosis of successive occupants of an isolated farm house; deaths from tuberculosis by age periods; the annual cost of tuberculosis to the State and to the people thereof as compared with the annual value of certain agricultural products; the amount appropriated by the State of Pennsylvania exclusively for tuberculosis work from 1893 to the present time; the comparison of deaths and causes for the years 1906-07; the number of deaths from scarlet fever, measles, diphtheria and whooping cough for the year 1907; the deaths from suicide and heart disease for 1907; the treatment for diphtheria by antitoxin during the years 1906-07. In connection with this exhibit a plan of the first floor of the State Capitol building in Harrisburg, showing the rooms and space occupied by the Department of Health, was prepared and the titles of 42 photographs and 60 cartographs were executed.

Special inspection of the watersheds furnishing the supply to Hummelstown and Connellsville have necessitated the making of maps of the village of Hershey and of the boroughs of Ursina, Castleman and Berlin in Somerset county, respectively, the latter boroughs being on the upper head waters of the Youghiogheny River.

Some miscellaneous map making has been done in connection with pollutions at Devon, Girard borough and the northern vicinity of Pittsburg, in connection with a typhoid outbreak at Royersford and Spring City, in connection with the problem of investigating the various water supplies in southeastern Pennsylvania, and in connection with the consideration of sanitary problems in southeastern Pennsylvania.

Besides the preparation of the various maps enumerated, statistical and other sheets were made for compiling nuisance reports, typhoid epidemic statistics and certain medical reports.

Reference to maps made in connection with Mont Alto work appears elsewhere in this report.

III. ENGINEERING.

The review of plans of proposed sewerage and water-works systems, and of extensions to existing systems, and the making of investigations and reports in relation thereto has been an important part of the work performed by the Engineering Division.

There were 306 sewerage and water-works applications received during the year, of which 107 pertained to water works and 199 to sewers. Of the water-works applications, 83 were received from private corporations and individuals, and the remaining 24 were sent in by municipalities. Of the sewerage applications, 26 were received from private corporations and individuals, and the remaining 173 were sent in by municipalities.

The water-works applications may be classified as follows: Thirty-two for ground water sources and 75 for surface sources; in 11 cases of which the plans provided for purification by filtration of

the surface water, and in 26 additional instances, the surface water was being filtered at the time the application for extensions were made, namely, in the following cases:

1 New Chester Water Company to supply water in Chester township, Delaware County, via Edgemont Water Company.
2 Armstrong Water Company of Kittanning.
3 McKeesport.
4 Springfield Water Company, suburban Philadelphia.
5 Bristol Water Company of Bristol.
6 West Side Water Company of West Bridewater.
7 College Hill Borough Water Company, College Hill.
8 Freedom Water Company of Freedom.
9 Union Water Company of Beaver Falls.
10 Fallston Water Company of Fallston.
11 Beaver Valley Water Company of Conway.
12 Patterson Heights Water Company of Patterson Heights.
13 Valley Water Company of Rochester.
14 North Rochester Water Company of North Rochester.
15 New Brighten Water Company of New Brighton.
16 Chambersburg.
17 Steelton.
18 Reading.
19 Pittsburg.
20 Warren Water Company of Warren.
21 Huntingdon Water Company of Huntingdon.
22. New Bethlehem.
23 Danville State Hospital of Danville.
24 Danville State Hospital of Danville (2nd application).
25 Cambridge Springs.
26 Reading (2nd application).

The applications for water filtration plants, arranged in order of date of receipt, are given below:

1 North East, Erie county.
2 Ridgway, Elk county.
3 Pottstown Gas and Water Company, Montgomery county.
4 Ellwood Water Company, Lawrence county .
5 Freeport Water Company, Armstrong county.
6 Mechanicsburg Gas & Water Company, Cumberland county.
7 Natrona, Allegheny county.
8 Riverton Consolidation Water Co., Cumberland county.
9 Shirmanstown Water Company, Cumberland county.
10 Riverton Consolidated Water Co., Cumberland county (2nd application).
11 Morganza, Washington county.

The sewerage applications may be classified as follows: Eighty-one for separate systems for sewage only, 82 for combined systems to receive both sewage and storm water, and 33 for sewage disposal works, and 3 for extension of time.

The application for sewage disposal plants, arranged in order by dates, are given below:

1 Allegheny City Home, Allegheny county.
2 Butler, Butler county.
3 Allentown, Lehigh county.
4 Palmer Land Company, Carbon county.
5 State Homeopathic Hospital for the Insane, Lehigh county.
6 Derry, Westmoreland county.
7 State Hospital for the Insane, Danville, Montour county.
8 Reading, Berks county.
9 Allegheny City Home (2nd application).
10 Pitcairn, Allegheny county.
11 College Hill (Robert A. Whiteside), Beaver county.
12 Devon, Chester county.
13 Haverford College, Montgomery county.
14 Williamson Trade School, Delaware county.
15 Reading (2nd application).
16 Cheswick, Allegheny county.
17 White Haven Sanatorium, Luzerne County.

18 South Canonsburg, Washington county.
19 Canonsburg, Washington county.
20 Bryn Athyn, Montgomery county.
21 Pennsylvania Training School for Feeble Minded Children, Elwyn, Delaware county.
22 J. W. & A. P. Howard Tannery, Erie county.
23 Beechwood Park Amusement Company, Delaware county.
24 Girl's House of Refuge, Delaware county.
25 Ellwood City, Lawrence county.
26 Cheswick (2nd application).
27 Edwardsville, Luzerne county.
28 Milton, Northumberland county.
29 Morganza, Washington county.
30 New Wilmington, Lawrence county.
31 Western Penna. Hospital for Insane, Dixmont, Allegheny county.
32 Meadville, Crawford county.
33 Bryn Athyn (2nd application).

Three applications for extension of time to fullfil the terms of permits issued to the borough of Youngville, Emporium and Oil City were made by these places.

306 applications received during the year, 247 have been examined and reported upon besides two applications left over from 1905, 2 from 1906 and 64 from 1907, making a total of 315 applications investigated and reported upon during the year. In 201 cases conclusions have been reached and a permit or decree duly issued by the Commissioner of Health.

Of the 201 cases, 72 related to water-works and 129 to sewerage and sewage disposal works.

With respect to water-works permits or decrees, 49 embrace surface sources, of which in 22 cases adequate filtration was required, and 23 embrace ground sources. The 22 cases where filtration was required are stated below in order of issuance:

1 Hummelstown Consolidated Water Company, Dauphin county.
2 York Water Company, York county.
3 Dauphin Consolidated Water Supply Company (Enola), Cumberland county.
4 Ridgway, Elk county.
5 Warren Water Company, Warren county.
6 Pottstown Gas and Water Company, Montgomery county.
7 Ellwood Water Company, Lawrence county.
8 North East, Erie county.
9 Danville State Hospital, Montour county.
10 Pittsburg, Allegheny county.
11 Shiremanstown, Cumberland county.
12 Riverton Consolidated Water Company, Cumberland county.
13 Danville State Hospital (2nd application), Montour county.
14 Freeport Water Company, Armstrong county.
15 Mechanicsburg Gas and Water Company, Cumberland county.
16 Fairchance, Fayette county.
17 Shiremanstown Water Company (2nd application), Cumberland county.
18 Riverton Consolidated Water Company (2nd application), Cumberland county.
19 McKeesport, Allegheny county.
20 Riverton Consolidated Water Company (3rd application), Cumberland county.
21 Western Pennsylvania Reform School (Morganza), Washington county.
22 Natrona Water Company, Allegheny county.

All but numbers 1, 2 and 16 are mentioned in the above list of 1908 applications.

With respect to sewerage decrees, 32 involved sewage disposal works and the other 97 related to sewers and ultimate treatment plants, as more fully hereinafter appears. Sewage disposal applications in 6 instances are pending, namely, Nos. 2, 10, 11, 27, 28 and 32.

A brief summary of the applications received and acted upon relative to water-works and sewerage since the inauguration of the Department is given below:

Applications received in 1905 and 1906,	155
Applications received in 1907,	236
Applications received in 1908,	306
Total,	697
Applications acted upon in 1905 and 1906,	74
Applications acted upon in 1907,	159
Applications acted upon in 1908,	266
Total,	499

There were 123 applications pending at the end of 1908. Fifty-six of them were water and 67 sewerage and disposal applications; 34 of the water-works and 19 of the sewerage applications were investigated, leaving 70 to be investigated.

The 697 applications comprise 212 water-works and 485 sewerage systems; 426 of the latter were municipal plants and 58 private works; and of the former, 165 were owned by private and 47 by municipal corporations. It may be interesting to note that 67 of the water applications concerned ground sources, and 146 concerned surface sources in 33 instances of which the water was being filtered, and in 24 cases new filterers were contemplated. Also with respect to the sewerage applications, 188 related to separate sewers, 212 to combined sewers, 9 to separate and combined, and 73 to disposal works, 3 having been for extensions of time.

So it appears that plans for 58 water filters and 73 sewage treatment plants have been considered and passed upon or will engage the attention of the Department at an early date.

WATER WORKS.

Water Works Permits and Decrees Issued by the

COMMISSIONER OF HEALTH

Up to January 1, 1909.

This work has been done under Act 182, approved April 22, 1905. The law is entitled, "An act to preserve the purity of the waters of the State for the protection of the public health." The term "Waters of the State" is defined to include all streams and springs, and all bodies of surface and of ground water, whether natural or artificial, within the boundaries of the State.

Acting under this law, which prescribed that no waterworks for the supply of water to the public shall be constructed or extended, or an additional source of supply be secured, without a written permit, to be obtained from the Commissioner of Health, the scope of inquiry in each case has been strictly confined to whether the supply be prejudicial to public health.

The virgin waters of the State are pure. They gather in their devious courses on or below the surface of the ground foreign matter, oft times of a poisonous character. To preserve the purity absolutely is impossible, but approximations may be achieved. The results frequently concern the removal of impurities injurious to public health under conditions demanding continual supervision by the State.

Precedent to judgment in any particular case, the full information as to the source of supply and capacity, the manner of collection and the means of distribution, is indispensable; with respect to the source, principally as to danger to be guarded against and means necessary for protection; with respect to capacity, because, besides other reasons, where a supply be altogether good and limited, consumers may be compelled by shortage to have frequent recourse to private wells and neighborhood springs in close proximity to and polluted by cesspool or privy drainage, or other sewage contamination, or because recourse may be frequently had to a polluted stream as the supplementary supply, and thus spread disease in the town, conditions which the law does not contemplate the State authorities should overlook or sanction; with respect to details, because, besides other reasons, the interests of the public health require that ample facilities for quick drainage or shutting off of any infection in any part of the system shall be provided, or where a filter may amply purify water in ordinary times, during a fire the speeding up may be at a rate entirely beyond the purifying capacity and thus sewage water may be introduced into town, or direct recourse may be had to raw creek water for emergencies.

In connection with the subject, it may be important to know about the private wells and springs in the town.

For the dissemination of information, the permits set forth quite fully the local situation leading up to the conditions under which an additional source of supply or an extension to existing water-works will not be prejudicial to public health.

The stipulations refer to provisions for removal of sources of pollution, protective measures, such as sanitary patrol of water sheds and reports thereof, efficient operation of purification works, remedial measures to be adopted by approval or advice of the Commissioner of Health in case the supply or any part of the water-works system becomes prejudicial to the public health and other matters, all appearing in the various cases herein set forth in full and arranged alphabetically.

ANNVILLE, LEBANON COUNTY.

Annville Water Company.

This application was made by the Annville Water Company of Annville, Lebanon county, and is for permission to increase its source of supply of water to the public in said village.

Annville, Lebanon county, is a village of twenty-five hundred population, located immediately south of the Lebanon Valley Branch of the Philadelphia and Reading Railway five miles west of Lebanon city. Part of the village is in North Annville township and part of it is in South Annville township. The sources of supply of water to the public are derived wholly from the hillsides immediately north of the village and in North Annville township.

There are two small runs which come down from the hills towards the village. One of them passes under the railroad near the passenger station opposite the central part of the village. Formerly the only supply was taken from the ground

up this ravine. The water flowed from natural springs up through openings in the bottom of a masonry reservoir thirty feet wide, fifty feet long and about ten feet deep. When these springs became insufficient, three wells were driven adjacent to the reservoir and pumps were installed to raise the water. The contributing area above is an uninhabited district. The elevation of the reservoir is sufficient to afford a gravity supply to the village, the water being conducted by an eight-inch pipe about one mile long. This source, while of excellent quality, proved insufficient in quantity, and on November ninth, nineteen hundred and five, the Commissioner of Health issued a written permit for an additional water supply, which has since been installed.

The new source is about one mile distant from the village in the second run whose area adjoins and is immediately east of that of the first source. It comprises a watershed approximately one-third of a square mile in extent, hilly and cultivated, at the outlet of which exist several springs. The water company acquired the right to the waters of these springs, improved and walled them up and conducted the water to a storage reservoir, located just above the ice pond. This reservior was to be built of masonry, and to be fifty feet long, thirty feet wide and about ten feet deep. An eight-inch gravity supply main delivers the water from this reservoir to the village, following the line of the run past the ice pond. The property here belongs to the Meyer estate, whereon is a dwelling, privy and barn near one of the springs. Above the Meyer Estate is the farm of Samuel Kettering.

The terms and conditions of the written approval and permit for this additional supply issued by the Commissioner of Health were as follows

FIRST: That all surface and run water be excluded from the springs, and for this purpose each spring shall be dug out and walled up in masonry to a sufficient height, and the adjacent land where boggy shall be sufficiently drained. The water from said springs shall be piped to the collecting and storage reservoir, and each such pipe leading from each individual spring shall be fitted with a gate permitting each said individual spring, or any or all of them, to be shut off separately or collectively from the said storage reservoir.

SECOND: That the proposed storage reservoir be made tight on the bottom and sides, and the walls thereof be carried up high enough to always exclude surface and run water, and that a drain shall be constructed so that the reservoir may be readily emptied and the waters therein wasted into the run; and a gate shall be placed on the supply main between the reservoir and the village so that the supply from the proposed source may be shut off when occasion may require it.

THIRD: That the present connection between the supply main and the ice pond shall be taken out, and that on no occasion shall the waters from said ice pond or any surface water be introduced into the Annville water supply system.

FOURTH: That the water supply company shall not be required to supply the said ice pond with spring water at any time, except as required by the contract and agreement with the said David H. Meyer, the owner of the said ice pond.

FIFTH: That the spring upon the said David H. Meyer Estate shall not be taken or used by the water company until the small tenement house and the buildings thereon are vacated, and that these buildings shall be removed on or before the first day of July, one thousand nine hundred and six.

SIXTH: That facilities be provided whereby the system of distributing pipes in the village may be easily and completely drained whenever occasion may require it.

SEVENTH: That permission to use the proposed additional source of supply is hereby granted under the above stipulations and provisions, and under the further provision and stipulation:

"That the said Annville Water Company, on or before the first day of December, one thousand nine hundred and five, shall file with the Commissioner of Health a complete plan of the entire water works system, present and proposed. This plan shall show the streets of the village, the location of the water pipes, their sizes, location of gates and hydrants, and the location and profile of the supply mains and any gates upon them, together with plans, sections and elevations of the storage reservoir, their gates and appurtenances, of the pumping station and the driven wells, a plan and section of the ice pond, and a topographical map of the watersheds of the two sources—the old and the new—said topographical map to be drawn to scale, giving elevations and locations of the springs and all the buildings upon the watersheds, highways and runs."

The company has submitted a plan showing the distributing pipe system and the water shed and the location thereon of dwellings, roads, et cetera, and a general plan of the pipe arrangement for the collection of the water supply from the springs and its delivery to the reservoir, but the detail plans of the springs, piping and reservoir have not been submitted.

It appears that during the dry season the present combined sources are inadequate for the need of the district in which the company has laid its pipe lines and to which it is furnishing water. Furthermore, the petitioners know of no available water that can be procured at the present time, except that to be obtained by drilling or boring wells. The petitioners, therefore, purpose to drill a well along the line of the new or east supply pipe line at a point fifty-five feet eastward from the valve immediately below the ice pond. The well is to be bored to such a depth as shall secure a proper and adequate supply of water. Its diameter is to be from eight to twelve inches, to be cased throughout with iron pipe, the outlet

to be of such elevation as to prevent any surface water from flowing into the well. It is proposed to install a pump in connection with the said well or wells, if there be more than one.

It has been determined that the proposed additional source of supply will not be prejudical to the public health under certain conditions, and a permit is hereby and herein issued therefor under the following conditions and stipulations:

FIRST: That an accurate record of the strata encountered in sinking the wells shall be kept and furnished to the State Department of Health, and that before the water is turned into the water district the water company shall notify the Commissioner of Health of its readiness to do so, whereupon the State Department of Health will collect samples of water from the wells and make tests thereof, and if found satisfactory, approve the supply.

SECOND: Before the additional supply is used, the water company shall prepare the detail plans heretofore called for but not yet submitted, of the reservoirs, springs, pond and pumping station and file the same, together with detail plans of the wells herein approved, their piping, the pumping station layout and appurtenances.

THIRD: At the close of each season's work, the water company shall file a plan of the extensions of the pipe lines in the streets laid during the year, with any other information in connection therewith that the Commissioner of Health may require, to the end that the said Commissioner shall always be informed of the extent of the water works and its use by the public.

FOURTH: If, at any time, in the opinion of the Commissioner of Health, the water works system, or any part thereof, of the sources of supply, shall have become prejudicial to public health, then such remedial measures shall be adopted by the water company as the Commissioner of Health may advise or approve.

It is the purpose of the State Department of Health to make regular inspections of the water works system and the water company shall assist in such inspection, and the company shall keep on blank forms satisfactory to the Department weekly reports of the operation of the water works system and file the same in the office of the State Department of Health.

Harrisburg, Pa., May 11, 1908.

ANNVILLE VILLAGE, LEBANON COUNTY.

(Annville Water Company.)

This application was made by the Annville Water Company of the village of Annville, Lebanon county, and is for permission to increase its supply of water to the public in the said village.

The drilled well for which a permit was issued by the Commissioner of Health on May eleventh, one thousand nine hundred and eight, was completed and found to yield at best about forty gallons per minute. This supply was not sufficient in the opinion of the company to warrant the expense of raising the water.

At the close of the extraordinary drouth of the summer and fall of one thousand nine hundred and eight the springs which are the source of gravity supply to the company are now in a very much depleted condition, and there is necessity for an immediate augmenting of the supply.

The petitioners propose to do this by collecting the ground water at and above the main collecting basin on the Meyers Estate, and also on the Kettering Estate, Along the bottom of the ravine it is proposed to lay open-jointed, vitrified pipe, to fill in around with crushed stone and then to cover all over with earth, bringing this up to the general surface of the ground so that the ravine will be entirely obliterated The water in the ground roundabout which flows out at the present time into the ditch from numerable points will thus be collected in the pipes, made available for the supply, to the village. The water will be piped into the main collecting reservoir now in use. Spring number six is right below Kettering's house. It is to be walled up and covered over and the water is to be piped to a two-inch iron pipe into the main feeder to the collecting reservoir. Thus the possibility of any surface contamination will be done away with. A part of the flow from spring number six will be delivered into the water trough at the Kettering farm, and the details of this arrangement are shown on the plans submitted for approval.

From spring number five the ravine or gulley down through the Kettering farm is to be treated in the same manner and for the same purpose as described with respect to the ravine on the Meyers Estate, and this water is to be conducted into the main collecting reservoir.

The Kettering privy is to be rebuilt and a masonry tight vault provided so that no possibility of sub-soil contamination of the water can occur.

The petitioners present at this time detailed plans of existing reservoirs and springs so that there is now on file in the Department all the information which has been called for.

It has been determined that the proposed additional source of supply will not be prejudicial to the public health, and a permit is herein and hereby issued therefor under the following conditions and stipulations:

FIRST: That the company shall pay especial attention to the prevention of any surface water getting into the system of underground collecting pipes herein approved. Such an occurrence is possible and likely if the gullies should be washed out.

SECOND: The Department will make systematic collections of samples of water from the water company's source of supply, and if the examinations of the samples should indicate any contamination whatsoever, then the water company shall adopt such remedial measures as the State Department of Health may advise or approve.

This permit is issued under the conditions and stipulations applicable thereto contained in the former permits issued by the Commissioner of Health to the Annville Water Company.

Harrisburg, Pa., December 23, 1908.

BERWICK, COLUMBIA COUNTY.

Berwick Water Company.

This application was made by the Berwick Water Company of the borough of Berwick, Columbia county, and is for permission to increase its source of supply and to extend water works in its water district.

Berwick borough, eight thousand population, a community composed largely of foreigners, and supported by one great industrial concern, the American Car and Foundry Company, lies on a comparatively level plateau, sixty feet or more higher than the Susquehanna river and on the north bank thereof. The incorporated territory is about one mile square. It is in the extreme eastern part of the county of Columbia, and is bounded on the west by the borough of West Berwick, population, three thousand, and rapidly growing, on the north and east by Briar Creek township, and on the east for a short distance near the river banks by Luzerne county. The settlement in Briar Creek township, where one thousand people reside, is known as North Berwick.

On the opposite or south bank of the river and in Luzerne county is the borough of Nescopeck, connected by a highway bridge to Berwick. In this settlement of about eighteen hundred people there are approximately three hundred and fifty dwellings. Excrement is disposed of in privy vaults, there being no sewer system. Slops are thrown out on the surface of the ground, which is porous. Ten cesspools are reported and five small private sewers. The latter empty into the river at convenient points. The velocity of the stream here is quite rapid. Probably sewage from Nescopeck does not pass across the river to the pumping station in Berwick. The streets are quite thoroughly piped for public water, and these pipes are owned by the Nescopeck Water Supply Company. This company purchases water of the Berwick Water Company, there being a six-inch main under the river, connecting both systems.

West Berwick borough was recently incorporated out of Briar Creek township. The houses are of frame construction and the owners are mostly employed in the mills. There are no sewers, but the streets are piped for public water and the mains are owned by the West Berwick Water Supply Company, which company buys the water of the Berwick Water Company.

The Berwick Water Company was chartered by legislative enactment of January twenty-seventh, one thousand eight hundred and eighteen, on which date the borough of Berwick was erected. Under this act the company was formed, and it was incorporated by the Governor on March thirteenth, one thousand eight hundred and eighteen. The company was bound to introduce water into the borough and to erect hydrants to use for extinguishing fires. It is a matter of history that the works were built in one thousand eight hundred and forty-eight, the supply being taken from a spring on the river bank and pumped into a standpipe.

In contemplation of the increase of stock and extensive improvements to the system, the company accepted the General Corporation Act of eighteen hundred and seventy-four in eighteen hundred and eighty-nine, and proceeded to obtain an additional source of supply, which is still in use.

The West Berwick Water Supply Company was incorporated under the laws of the State in nineteen hundred and two to supply water to the public at the village of West Berwick in the township of Briar Creek, Columbia county.

The Nescopeck Water Supply Company was incorporated under the laws of the State in eighteen hundred and ninety-four to supply water to the public in the township of Nescopeck, Luzerne county. The incorporators of the last two companies were men or officers interested in the Berwick Water Company.

The Nescopeck Water Company was incorporated in eighteen hundred and ninety-one to furnish water for domestic and manufacturing purposes to the public in Nescopeck, Luzerne county. This company was dissolved by decree of the court in July, nineteen hundred and one.

The Briar Creek Water Company was incorporated in May, nineteen hundred and one, to supply water to the public in the township of Briar Creek, Columbia county. So far as the Department is informed, this company has not erected water works or attempted to supply the public with water. The incorporators may not have any interest in the Berwick Water Company. However, the incorporators of the Briar Creek Water Supply Company, approved March twenty-fifth, nineteen hundred and four, for the purpose of supplying water to the public in said township of Briar Creek, appear to have been the officers or men interested in said Berwick Water Company. It is presumed that the water pipes laid in the streets

in the village of North Berwick and the township of Briar Creek are the property of the Briar Creek Water Supply Company, since the Berwick Water Company, so far as the Department is informed, does not have a right to sell water to the public in this district. However this may be, the Briar Creek Water Supply Company has not made a report and filed plans of its water works system in the State Department of Health.

The West Salem Water Supply Company was chartered in nineteen hundred and three for the purpose of supplying water to the public in the township of Salem, Luzerne county, Pennsylvania, the incorporators being men interested in the Berwick Water Company. It is not known to the Department that this concern has laid any water works pipes, or attempted to supply the public with water.

So it appears that the Berwick Water Company supplies water to the West Berwick Water Supply Company, to the Nescopeck Water Supply Company and to the Briar Creek Water Supply Company, a district in which reside about fourteen thousand people.

Berwick borough has a combined sewer system. It practically encircles the town and the sewage is discharged through a five-foot circular drain into the river at the foot of Oak Street near the boundary line between Berwick and West Berwick. There are over fifteen hundred buildings in the town. In nineteen hundred and five less than two hundred of them had sewer connections. Cesspools are common. The soil is light and gravelly.

The lower or main plant of the American Car and Foundry Company is located in the western part of the borough, west of Oak and Vine Streets, and is partly in Berwick and partly in West Berwick. It comprises the rolling mill, steel works, wheel, forge, paint and smith shops and foundry, where the vast majority of workmen are employed. The upper plant, where the frame and wood work is done and the castiron pipe is made, is in the eastern central part of the borough.

The Berwick Water Company has three sources of supply, namely, Glen Brook, Verners Run and two alleged springs at the edge of the Susquehanna River in Berwick borough.

On Glen Brook and Briar Creek township there are two reservoirs situated about two miles north of Berwick. Both of them are artificial. The lower one holds eight million four hundred and twenty thousand gallons, is termed Reservoir Number One and is used for impounding purposes. Reservoir Number Two holds three million five hundred and twenty-eight thousand gallons, and is used largely as a subsidence basin. The watershed comprises two and eighty-two hundredths square miles. It is rugged country. Two streams unite above the upper basin to form the main stream. The source of each branch is a number of springs near the foot of what is known as Lee Mountain. On the east branch there are seven occupied homesteads. On the west branch there are twenty dwellings, one school-house, two churches and a store. All the buildings on this branch, except eight residences, are in the little village of Summerhill, on the extreme western edge of the watershed.

Ordinarily, when there is plenty of flow, the water is taken directly from the stream above reservoir Number Two and piped to the town. The supply main from the lower dam to Berwick is twelve inches in diameter, and a parallel one is twenty inches in diameter, each sixty-two hundred feet long to the borough line, where they connect with the distribution system. On the way they pass through the village of Foundryville and the village of North Berwick. In each place the pipe lines are tapped several times.

The reservoirs are fenced in, and a man who lives in the neighborhood below the dams is constantly employed on patrol duty.

On Verners Run, in Salem township, Luzerne county, distant about a mile and a half due east of the Glen Creek reservoir, is Reservoir Number Three. It is smaller than number one, but sufficiently high to furnish a gravity supply to the borough. The source of this stream is also a number of springs at the foot of Lee Mountain. On the watershed, which is two and fifty-three hundredths square miles in extent, there are eight occupied estates, one church, one creamery and a schoolhouse. This area is also patroled by a man in the employ of the water company. He resides on the watershed about half a mile above the reservoir. From the dam a ten-inch supply main, thirteen thousand four hundred and fifty feet long, extends to and connects with the twelve-inch pipe line from Glen Brook reservoir. The juncture is near North Berwick at a point about five thousand feet below Reservoir Number One. There are a few taps off this ten-inch line.

The patrols are maintained because the water company realizes that pure water infected by nascent fecal matter becomes most dangerous and that, therefore, such poisons accidently put into the streams on the steep slopes of the mountain shed might reach the water district in a short time and cause disaster.

The two springs, so called, at the edge of the Susquehanna River in the central part of the borough, and at or near the low water mark of the river, are covered over with long, narrow, cast-iron, water-tight boxes, about thirty-six feet long and seven feet wide and deep, open on the bottom lengthwise. These boxes were placed in the gravel over the springs and the sides thereof were imbedded several feet in the gravel. The expectation was that only water which passes up through the gravel into the boxes flowing from the alleged springs would enter the boxes. The box nearest the shore is on the edge at low water, and it is about one hundred feet from the bank at high water. In this box about midway thereof is a small box, about three feet square and seven feet long, filled with stone. A perforated sixteen inch pipe extends out through one end of the main box to a three-million gallon

pumping engine in the nearby pump house. This is the pump suction pipe by means of which water is drawn from the alleged spring and forced directly into the water district. Until recently and as occasion required, this water was delivered into the system of street pipes in the town.

The second box, not now in use, is located about seventy feet further out in the stream. It was formerly connected by twenty-four-inch pipe to the first box.

In the fall of nineteen hundred and five, when firteen inches of water stood over the intake, at least one leak in the cast-iron pipe was observed by a Department officer and evidence of downward currents could be seen. As the river rises and the pressure increases, the leaking and the infiltration downward and thence upward through the gravel into the intake chamber correspondingly increases undoubtedly. It is safe to conclude that all of the water which flows into the intake does not come from the supposed underground flow.

The sixteen-inch force main from the pump house reduces to a ten-inch main at the corner of Market and Third Streets, and thence it is a ten-inch pipe all the way to the lower works of the American Car and Foundry Company, with a four-inch branch, to the upper works of said company. There is a connection between the force main and the town system of pipes at the corner of Market and Third Streets, and two others in Third Street near the said lower works. They are provided with valves, kept closed. There is no way to introduce river water into the town system except by opening these valves. There is a check valve at the upper works and also at the lower works of the American Car and Foundry Company, which prevents river water from flowing into the town system, but admits the mountain water to the industrial plant when the pumps stop or the pressure on that side is reduced for any reason.

The river water is now used exclusively for industrial purposes, except at such times as the mountain supply has become depleted and it becomes absolutely necessary to put the river water on the town to obviate a water famine. Then the local authorities and the public are amply warned to boil all water. It is to obviate this necessity that the water company purposes to increase its mountain supply.

At both works of the American Car and Foundry Company there are independent lines of water pipes laid to the different mills and shops, through which the mountain water is supplied for drinking purposes. Warning signs are placed throughout the works calling attention of employes to the danger of drinking the water supplied to and used in the works for industrial purposes.

The supply to West Berwick and to Nescopeck and to North Berwick is taken off the town distributing pipes so that whatever water is supplied generally throughout Berwick is also supplied to these other places. For all purposes the consumption averages two million one hundred thousand gallons daily, of which one million four hundred thousand gallons is for manufacturing purposes, and is largely used at the lower plant. The water company supplies the town and shops exclusively with mountain water as long as this is practicable. This, of course, saves pumping. The next arrangement of operation is to pump river water to the lower industrial plant and possibly the upper plant, keeping the town exclusively on the mountain water. Finally, when the mountain water supply becomes prejudicial for town purposes, recourse is then had to the river source to make up the deficiency.

There is a second pumping engine in the station. It has a capacity of about one million five hundred thousand gallons. It is held in reserve for fire protection.

Thus it appears that there is a domestic system and an industrial system of water works in the district, they being interchangeable. It is also noted that ordinarily the river water is supplied largely to the lower industrial plant.

During August, September and October of nineteen hundred and five, following the outbreak of typhoid fever at the river town of Nanticoke, a few miles up stream, typhoid fever broke out among the men employed at the lower works in Berwick, and it did not disappear until pure water had been furnished at the works and the epidemic had assumed proportions great enough to scare the employes into the observance of rules against drinking river water. Out of ninety-two cases reported, sixty-three were among men employed at the lower works. The other twenty-nine cases included eleven women, six boys and two girls, and ten men variously employed in the town or surrounding country. Had the infection been in the domestic supply, men, women and children everywhere in the district should have been poisoned, which was not the case.

The petitioners purpose to build a new reservoir on Glen Brook, using the present reservoirs there and build an additional supply main from Verners Run dam to the new dam on Glen Brook. The Susquehanna River affords an abundant supply but because its waters are polluted by sewage from many cities along its banks above Berwick and because the cost of purifying this water and pumping it would be prohibitive, the water company prefers to develop the mountain supply to provide for double the present population of the district. On the basis of a per capita consumption for industrial purposes of an amount equal to that now furnished, a supply capable of yielding three million gallons daily is sought.

The proposed plans are intended to afford a sufficient gravity supply from the mountains to meet all domestic consumption throughout the year and as much more as may be possible in order to minimize the use of the river water for industrial purposes.

With the present impounding capacity of fifteen million gallons, in round numbers, it is only possible to store eight days' supply for the domestic consumption of twenty-three thousand people. There are often periods of drought when this amount

of storage plus the minimum yield of the watersheds would be totally inadequate to avoid a water famine. The petitioners estimate that with a daily domestic consumption of one million eight hundred and forty thousand gallons and an extreme low run-off of six hundred and ninety-two thousand four hundred and thirty-four gallons for a period of fifty-four days, a storage of fifty million gallons of available water should be assured to supply the domestic consumers, the pumps being used during this period to meet the industrial consumption.

To accomplish this purpose it is proposed to build a third dam across Glen Brook valley about seven hundred feet below dam number one. It is to be forty-seven feet high to the top of the embankment, have a concrete core wall, reinforced by earth embankment to be two hundred and sixty feet long with a flood channel on one side, spillway in the centre and a gate house at the foot of the embankment in the reservoir, submerged, with screens on the outside, provided with three ports at different depths. From the gate house the supply mains to the town are to extend. A blow-off pipe at the bottom is provided. This structure will impound twenty-three million eight hundred thousand gallons.

Dam Number One is about twenty-one feet high and one hundred and ninety-five feet long. Dam Number Two is fifteen feet high by two hundred and thirty feet long. Both are earthen embankments, Number One having a concrete core wall. As the waters from the brook run directly into the upper reservoir during a rain storm, the bottom is well filled with mud. Provision is made for carrying the flood waters around Number One Reservoir through an open conduit, roughly made in the side of the hill. When this ditch was constructed, gates were built at its entrance to control the floods and turn the waters into either reservoir, but at present there is no arrangement by which flood water can be conserved in periods of drought or whenever desired. So no advantage is taken of summer showers, from which much good water might be impounded to tide over a drought.

It is proposed to clean out reservoirs number one and two to give a minimum depth of water in number one reservoir of ten feet and a maximum of twenty-six feet, and a minimum depth of ten feet in number two reservoir and a maximum of thirteen feet. In the new reservoir, number four, the minimum depth of water is to be twenty-six feet and the maximum forty-two feet. By this arrangement fifty-three million gallons of water is to be impounded as follows: In the present Verners Run reservoir, three million three hundred thousand gallons; in reservoir number one, nineteen million four hundred thousand gallons; in reservoir number two, six million five hundred thousand gallons, and in the proposed reservoir, twenty-three million eight hundred thousand gallons available draft.

At dam number one it is proposed to tear out the old gate house, substituting therefor a new one similar to that proposed at dam number four. At dam number two it is purposed to construct a controlling chamber by means of which, through various pipes, the water from the main stream above may be delivered into any one of the three reservoirs on Glen Brook or into the supply mains in the town. At the head of reservoir number two there is to be a small feed dam with gates on the pipes which pass beneath the dam to the control chamber at dam number two.

In each one of the several dams a spillway mid-length of the dam will be provided. It is proposed to conduct the flood waters around all these structures by an improvement in the existing flood channel and by extensions of the same. It is to be an open channel, graded and lined with concrete sides and on the bottom, to dam number one. From this point to below the lower dam it is to be a sixty-inch reinforced concrete conduit built in the side hill.

From observations made on the ground it is known how much of a precipitation renders the waters yielded from the watershed objectionally turbid. There is to be an automatic flood gate arranged in a chamber in the flood channel at dam number two, whereby all water of such turbidity is diverted from reservoirs number one and four, and wasted.

It appears that ample drainage facilities are provided for the independent drainage and cleansing of each basin.

In order to use or utilize all the dry weather flow from Verners Run watershed, it will be necessary to provide a pipe leading from said reservoir, which is forty-three feet at high-water mark above the high water in the proposed reservoir, into the latter. If there were a constant draft upon the Verners Run dam from the town, the present ten-inch pipe as now arranged and connected to the twelve-inch from the Glen Brook supply might carry all the mean dry weather yield from Verners Run, because the ten-inch pipe has a maximum capacity of nine hundred and forty-two thousand gallons per day. But such is not the case in practice, so that water flows over the spillway of Verners Run dam and is wasted when it is the most valuable. It is proposed to build a twelve-inch main paralleling the ten-inch main and connect the new twelve-inch main with the twelve-inch from Glen Brook. The old ten inch is to continue as now to connect with the twelve-inch to town, but this is to be in the future the only supply to the twelve-inch pipe to the town; therefore, there will be a direct supply main from Verners Run reservoir to Berwick and a direct supply main twenty inches in diameter from the Glen Brook reservoir to Berwick.

The observed yield for dry weather periods from the local watersheds, although high when compared to average watersheds, are still comparable with yields from mountain areas in Pennsylvania. The estimated flow and the contemplated storage are reasonably certain to accomplish an adequate supply of drinking water to a

population of twenty-five thousand people. What the industrial uses of water may be remains to be proven. It is clearly impossible to furnish the demands of both kinds of consumption from the mountain watersheds even now. It is more desirable to conserve the virgin pure waters for general town uses and to use the river water for manufacturing, than to supply all purposes from the river after first filtering such water.

It is easily possible by efficient patrol and the maintenance of sanitary conditions to keep the streams on the mountain pure and wholesome for domestic uses. The individual householder there is responsible for the proper disposition of poisonous waste. The water Company is responsible for the quality of water it furnishes to its consumers, which involves the exercise of due care in protecting its source of supply from pollution. And the State is responsible for the preservation of the purity of the streams for the protection of the public health.

It has been determined that the proposed additional source of supply will not be prejudicial to public health, and the same is hereby and herein approved and a permit issued therefor and for the extensions of water pipes in the borough of Berwick under the following conditions and stipulations:

FIRST: That detail plans of all of the dams, reservoirs, gate houses and chambers, location of piping, gates and appurtenances and detail plans and profiles of the supply mains leading to Berwick, as the same shall be upon the completion of the work herein approved, shall be prepared and filed in the office of the State Department of Health, together with any other inforation in connection therewith that may be required at the close of the seasons work.

SECOND: An accurate plan of the pipe lines, gates, hydrant locations, blow-off and drainage facilities, shall be prepared and filed in the office of the Commissioner of Health at the close of the current year. And, thereafter, annually, plans of all extensions made to the street pipe system and water works during the year shall be prepared and filed in said office, together with any other information in connection therewith that may be required, to the end that the Commissioner of Health may be informed of the extent of the water works system and the number of people supplied with such water.

THIRD: Adequate facilities for the quick drainage of every part of the water works system shall be afforded, and these drainage points shall be adequately designated on the plans to be filed with the State Department of Health.

FOURTH: The water company shall maintain adequate patrols of the watershed, to see that proper receptacles are provided and used and maintained on all occupied estates, and that all reasonable precautions be taken to prevent any contamination whatsoever of the waters to be supplied to the public. Monthly reports of all inspections shall be kept and copies thereof, to the satisfaction of the Commissioner of Health, shall be filed in said Commissioner's office.

FIFTH: If, at any time, in the opinion of the Commissioner of Health, the water supply of the water works or any part thereof has become prejudicial to the public health, then the water company shall adopt such remedial measures as the Commissioner of Health may approve or suggest.

SIXTH: Detail plans of the construction and installation of the check valves shall be prepared and filed with the Commissioner of Health. The water company shall make frequent inspections of these valves to see that they are securely seated, and that no river water can possibly pass by these valves into the town system. The only place where river water may be introduced into the town system of distributing pipes shall be at the three places above mentioned, namely, at the corner of Third and Market Streets and in Third Street near the lower industrial plant. However, the gates on these by-passes shall be securely closed and never used except in the face of a water famine, and not then unless the public, the local health officials and the State Commissioner of Health be notified and amply warned. The consumers shall be advised by the water company at such times to boil the water.

SEVENTH: The water company shall see to it that its consumers who use river water at industrial plants shall keep posted throughout the several mills, shops and places warning signs notifying all the employes of the danger of drinking the water supplied to the plant from the river.

EIGHTH: Regular inspections will be made of the water works system by a Department officer. The State Department of Health may suggest rules and regulations to govern the supply of water to the public in so far as the public health is concerned, and the water company shall co-operate with the Department and furnish facilities for inspections and assist in the examinations if required. The company shall keep a weekly report of the operations of the works on forms satisfactory to the Department of Health and submit copies thereof to the Commissioner of Health when required.

NINTH: It is expressly stipulated that this permit for an additional water supply and an extension of water works, relates only to the supply of water to the public in the borough of Berwick, or the territory defined by the company's charter. The mere ownership of stock in the West Berwick Water Supply Company, the Briar Creek Water Supply Company, the West Salem Water Supply Company and the Nescopeck Water Supply Company, in the absence of a purchase of the franchise and property of these independent corporations, or of a consolidation or merger under the laws of the State, does not entitle the Berwick Water Company to rightfully petition for approval of plans to extend water works for the supply of water to the public in territory outside of the borough of Berwick.

It is suggested that the Berwick Water Company might find it profitable to construct permanent weirs on Glen Brook above the reservoirs and to take daily observations of the yield of the watershed and of the amount of water supplied to the town. This might also be done on the Veners Run water shed. The first cost would be trifling and the daily observations would involve no additional expense to the company. The knowledge thus secured might prove of very great value to the company. The measurements are recommended.

Harrisburg, Pa., March 24th, 1908.

BETHLEHEM, NORTHAMPTON COUNTY.

This application was made by the borough of Bethlehem, Northampton county, Pennsylvania, and is for permission to install the necessary plant and to obtain an additional source of supply of water to the public within said borough.

It appears that on May twenty-seventh, nineteen hundred and seven, a decree was issued to the Board of Water Commissioners of the borough of Bethlehem by the Commissioner of Health, in which decree, after reviewing the circumstances, the Commissioner continued "I have determined that the present source of supply of water to the public in Bethlehem is prejudicial to public health, and, therefore, apprise the Board of Water Commissioners of the danger to the public accompanying the use of the existing source of supply and hereby advise and request the Water Commissioners to prepare and submit to the State Health Department for consideration, a plan or plans for the supplying of pure water to the public."

The Commissioner further determined "that on or before September first, one thousand nine hundred and seven, the borough shall comply with the law requiring the filing with the Department of plans and a report relative to its existing system of water works."

The petitioners report that the present supply has become inadequate since the annexation of West Bethlehem, and that an examination of all the possible sources within a radius of ten miles or more has proved them all to be either insufficient or entirely too expensive. The petitioners therefore determined to buy the Illick Mill property and to obtain thereon a supply of water from deep wells, which supply will supplant that now obtained from the limestone spring in the borough.

The Illick Mill property now in the possession of the borough comprises nineteen and five-tenths acres and stretches along the banks of Monocacy Creek for a distance of about three thousand feet up-stream from a point about a mile above Bethlehem and West Bethlehem, between which the creek is a natural boundary. On the property are Illick's dam and a mill privilege.

Above the site of the wells Monocacy Creek has a drainage area of forty-three square miles, ninety per cent. of which is said to be under cultivation. The upper part of this area is hilly, and here the geological formation is slate, while at the lower part of the area it is limestone and here the topography is gently rolling.

The Lehigh and Lackawanna branch of the Central Railroad of New Jersey follows the course of the creek, crossing and recrossing it. There is on the drainage area a population of forty thousand or more, ninety-four per square mile. There are also along the creek two boroughs, Chapman on the upper part and below it Bath, which latter is about ten miles above the site of the wells. Bath has now an estimated population of nine hundred. Around it, also on the watershed, are several large cement manufactories, and this recently-developed industry promises to considerably increase the population in the vicinity. In nineteen hundred and six there were in Bath several private sewers discharging into Monocacy Creek and a number of privies overhanging its banks.

The deep wells on the Illick Mill property are already drilled or in progress of drilling. They are to be below the dam to the west of Monocacy Creek, between it and the mill race. The creek here and for a mile or so above has moderately steep though not high side hill slopes leading to the comparatively flat territory beyond. The lower cell has been completed, being located about one hundred feet from the race and thirty feet from the creek, and just below an overflow from the former to the latter. It is said to have been drilled eight inches in diameter to a depth of seven hundred and fifty feet, and to have been lined to a depth of two hundred and fifty feet with seven-inch casing. The well is said to extend through limestone rock with layers of silicious rock. It is said that practically no water was found until a depth of two hundred and eighty feet was reached, when the well commenced to overflow, and it continued to do so in increasing quantities as the depth was increased. It is said that the natural flow rises to the height of eight feet above the ground at the rate of two hundred thousand gallons per day, and that the well yields nine hundred thousand gallons per day when the water in the well has been lowered twenty-seven feet below the ground; and further, that a continuous ten-day test with an air compressor yielding one million two hundred and fifty thousand gallons daily with a maximum rate of discharge of one million five hundred thousand gallons per day when the water was thirty-five feet below the surface of the ground, and further that bacteriological and chemical tests made at the University of Pennsylvania and Lehigh University proved entirely satisfactory.

The second well, in process of construction, is about two hundred feet west of the one just described and about sixty feet from the race and one hundred and thirty feet from the creek. It has been drilled twelve inches in diameter and lined with

twelve-inch casing to the depth of two hundred and fifty feet, below which the well is being continued eight inches in diameter. No tests have as yet been reported to the Department.

The elevation of the ground around the wells is, speaking roughly, five feet above the ordinary elevation of the water surface in the adjacent part of Monocacy Creek and five feet below the elevation of the water surface in Illick's dam. The mill is one hundred feet distant from the first mentioned well, and a barn and several dwellings are within two hundred feet of the well and somewhat further from the second well.

It is proposed to pump, presumably at least in part by water power, from the wells to a twenty-inch rising main nineteen hundred and twenty feet long to a proposed standpipe, to be located on an eminence between the wells and the town and having an elevation of approximately ninety feet above the wells and little or not at all above the highest parts of Bethlehem. From the standpipe twenty-two hundred and ten feet of twenty-inch pipe will extend southerly in or near a public road to the borough line, and will there be connected to the present mains. The pump station, force main, standpipe and supply main have not been designed in detail.

A serious conflagration in Bethlehem might, at any time, require water for fire fighting at the rate of two million gallons per twenty-four hours or more, in addition to the ordinary consumption of about one million five hundred thousand gallons per twenty-four hours, a total consumption of three million five hundred thousand gallons per twenty-four hours. The storage provided must, during the continuance of the maximum rate of consumption assumed, furnish water at the rate of one million gallons per twenty-four hours, the excess of this rate of consumption over the rate of the yield of the wells, liberal assumption as two million five hundred thousand gallons per twenty-four hours. It is not known what storage will be provided in the new standpipe in addition to the nine hundred thousand gallons provided in the two existing standpipes, but since these must also take care of the daily fluctuations in the consumption, a million gallons storage might be assumed to be always maintained, and this amount would be exhausted in eight hours by the assumed rate of consumption.

Therefore, it appears that the welfare of the community would demand additional storage and an additional source of supply of pure water, especially in view of the proposed extending of the distributing system into West Bethlehem.

That the pumps and wells might always be ready for service in case of fire, the layout of the proposed puming station should provide against any possible flooding of the machinery or surface pollution of the wells by high water in the creek.

Though the wells are deep and at a considerable distance from thickly built-up communities, it is not at all impossible that their water may, at some time, be polluted by the waters of Monocacy Creek or sewage of Bethlehem, more especially if the water in the wells is maintained at a considerable distance below the surface. Therefore, frequent bacteriological tests of this water should be made.

It is reported that the pressure in parts of the town is at present insufficient for fire fighting. Such information as has been submitted with the application does not indicate that any greater pressure would be obtainable in the proposed system.

It has been determined that the proposed source of supply will not be prejudicial to public health and it is hereby and herein approved that a permit therefor be issued under the following conditions and stipulations:

FIRST: Ample facilities shall be provided by means of blow-offs placed at all low points whereby the rising main, standpipe and supply main may be completely drained.

SECOND: Detailed plans of the layout at the pumping station and of the rising main, standpipe, and supply main showing all valves and connections, shall be filed with and appoved by the Commissioner of Health before work is commenced on these respective parts of the system and before water is supplied to the public from the new source, a description and, if necessary, plans of the construction of the wells shall be filed with the Commissioner of Health.

THIRD: After the proposed works are completed and the supply of water to the public from the proposed source has been commenced, water shall not be furnished to the public from any other source without a permit from the Commissioner of Health.

FOURTH: It is the purpose of the Department to obtain samples of water for analyses from the various parts of the system from time to time, and the petitioners shall render such assistance in carrying out this idea as may be necessary, and shall make such alterations in the system and source of supply as the Commissioner of Health may suggest or approve or demand in the interests of the public health to the end that the water supplied through the water-works of the petitioners shall not be prejudicial to the public health.

FIFTH: Detail records of the operation of the works shall be properly kept on blank forms to be suggested by this Department and copies thereof shall be furnished to the Commissioner of Health.

SIXTH: The permission herein granted is given under the express stipulation that the plans of the present works already called for in the decree of the Commissioner shall be filed with the said Commissioner of Health on or before September first, nineteen hundred and eight.

Harrisburg, Pa., Juy 16th, 1908.

BIGLER TOWNSHIP, CLEARFIELD COUNTY.

Madera Water Company.

This application was made by the Madera Water Company of Madera village, Bigler township, Clearfield county, and is for permission to obtain an additional source of supply of water to the public within its chartered territory and to extend water pipes in the streets of said village.

It appears that Madera is a mining settlement of about one thousand population, located in the center of Bigler township, Clearfield county, on Clearfield Creek.

This stream has its head waters in Cambria county at Cresson and Gallitzin boroughs in the summit of the Allegheny mountains. Thence it flows northerly through the county and through Clearfield county, joining the West Branch of the Susquehanna river near the county-seat, which is Clearfield borough. The territory so drained is mountainous. Madera is on the stream about fourteen miles above the county-seat. The direct means of communication between the two places is a branch of the New York Central and Hudson River Railroad. The village is also on the Moshannon and Madera branches of the Pennsylvania Railroad. The region round about is rich in deposits of bituminous coal and this resource is mined extensively. There are several operations in and about Madera. The principal ones are the Corona Coal and Coke Company, employing about two hundred men; the Morrisdale Coal Company, employing about one hundred men, and the Blyth Coal Company, employing about seventy-five men. There are about one hundred and sixty houses. Fourteen of them have private sewers to the runs. Otherwise, the shallow privy vault method of sewage disposal is in vogue. Sanitary conditions are of a low standard, but the general health of the community is good at the present time. There are three cases of typhoid fever, attributed to the use of contaminated well water.

Large quantities of sulphur water are pumped from the mines and drained into the streams in the region.

The Madera Water Company was chartered in nineteen hundred and four for the purpose of supplying water to the public in the village of Madera. During the year and the one that followed, the water works system was built, comprising springs, a storage and distributing reservoir and the pipe system in the village. The village is located on the east bank of the creek and on the north bank of a tributary called Alexander Run. The town site is on a side hill, whose summit is several hundred feet above the village. Numerous springs outcrop on this hill, and some of them are used as sources of individual supply to the citizens of the village.

Alexander Run rises about a mile and a half to the east and drains a very precipitous, small watershed, on which there are several mine operations. The company's water supply is three small springs. They are located about a mile and a half southeast of the settlement in the valley of a small brook, tributary to Little Muddy Run, which in turn empties into Clearfield Creek before Madera village is reached. These springs are enclosed in masonry, covered over and kept locked. There is no chance for surface drainage to flow into the springs. From two of them the water is piped through a four-inch pipe line, one line for each spring, terminating in a masonry reservoir, fifty-five feet long by thirty-six feet wide by six feet deep. The bottom is natural earth. The structure stores eighty-nine thousand gallons of water, and when full the surface elevation is seventy feet above the village. The reservoir is distant about one thousand feet from the two springs. A six-inch drain pipe is provided to empty the reservoir into the brook. A five-foot board fence closes the basin.

From the reservoir the water is conducted by gravity through a six-inch cast-iron pipe to the village, about a mile and a half distant. This pipe line follows the valley of Muddy Run and Clearfied Creek, and is laid in a highway.

Between the reservoir and the village the third spring is located. It is on the hillside to the east of the road, or main public line, and at elevation about equal to the reservoir elevation. The water is piped from it through a four-inch line into the six-inch gravity main leading to Madera.

There are three and a half miles of cast-iron pipe laid in the streets of the village. The diameters range from six to two inches. One hundred and ten houses are supplied. Probably eight hundred people reside in these dwellings. The remaining inhabitants obtain their drinking water from private wells and springs.

Formerly the water company furnished the Morrisdale Coal Company, but this service had to be discontinued owing to lack of supply.

The flow of the three springs above described does not exceed twenty-five thousand gallons per day during protracted dry periods. The watersheds above the springs are unpopulated. Eight years ago Madera had a population of two hundred. It is confidently expected that the village will rapidly increase in size because of the extensive mining operations now being developed in the territory. To meet the present requirements and increased demands for water consumption, the water company stands in need of an additional source of supply. Prior to the present season the three springs constituting the existing source were ample in flow to supply the people with drinking water, but the drought of the current season has practically dried up the springs. The inhabitants in the western section of the village at present are compelled to seek their drinking water from dug wells.

The three cases of typhoid fever in this locality are believed to be due to the use of this dug well supply. The use of ground or spring water taken from the vicinity of privy vaults and cesspools of the percolating type, where located on a hillside subject to surface flow contamination, is a suspicious practice. The interests of the public health demand that proper receptacles for sewage should be used in order to make impossible the escape of any sewage matter, either from the surface of the ground or underneath it, to the sources of drinking water supply.

The water company has no additional plans of its street pipe system showing the locations of pipes, hydrants, valves, drainage facilities and the sizes of the pipes.

The Madera Water Company purposes to build a collecting reservoir about a mile northeast of the village near the headwaters of a brook tributary to Alexander Run. The source is to be a spring. This spring is on the land of Joseph K. Minds. No plans have been submitted of the details of the reservoir, or of the proposed six-inch cast-iron pipe line from it to connect to the street pipe system in the village.

The petitioners, however, state that the new reservoir will be one hundred and seventy-five feet above the village, and that it will probably include a masonry dam, which will dam up the water to a depth of about six feet, storing about one hundred thousand gallons. At the site chosen it would appear that the watershed will have an area of less than three-quarters of a square mile. The land is heavily wooded and there is one occupied dwelling on the watershed.

It is impossible for the Department to give a fair consideration to a proposition of this kind when the petitioners neglect to submit adequate plans and data.

As the proposition now stands the new reservoir will be one hundred feet higher than the old reservoir. Therefore, the old reservoir must be abandoned, or there must be two services in the village, one a high service and the other a low service. Since there are fire hydrants distributed in the town, no one would desire to be on the low service district, and this would result probably in the entire village being put on the high service so long as the supply was capable of furnishing the water. Then the old service, or low pressure, would have to be resorted to for a part of the village. Or it may be that the water company intends to introduce an auxiliary pumping station or an intermediate collecting reservoir, to be placed at the same elevation as the old reservoir.

It seems that the details have not been thought over; the great haste at the present time being for an immediate supply of water to the village. The Department's representative measured the flow on the day of his inspection and ascertained it to be about fifty thousand gallons per twenty-four hours.

Within one hundred feet of the proposed new spring there is a dwelling and a shallow privy vault. By the construction of this vault and its proper maintenance, and by the walling up and proper protection of the spring there should be no danger of contamination, but the water company should attend to this.

It has been determined that the proposed source of supply will not be prejudicial to public health, and a permit is hereby and herein issued therefor, under the following conditions and stipulations:

FIRST: The water company shall on or before December first, nineteen hundred and eight, prepare and file in the office of the Commissioner of Health complete plans of the existing water works, showing reservoirs, springs, pipe line and watersheds thereabove, the supply mains and distributing pipes in the streets and all gates, hydrants and drainage and blow-off facilities.

SECOND: Provision shall be made at all low points for the drainage and flushing of supply mains and distributing pipes.

THIRD: The water company may extend its street pipe lines on the express condition that at the close of each season's work plans thereof, together with any and all information in relation thereto that may be required, shall be filed in the office of the Commissioner of Health, to the end that the State Department of Health may be kept fully informed of the extent of the water works system and the public use thereof.

FOURTH: The water company shall provide a masonry and water-tight privy vault on the property of Joseph K. Minds, and shall see that this is used and properly maintained, in order that all contamination of the proposed spring and reservoir shall be prevented.

FIFTH: That before the water company builds the reservoir it shall submit a detail plan thereof, which must be approved by the Commissioner of Health. From the area which it is proposed to flood with water all loam, mud and vegetable matter shall be removed. Plans shall include the contour of the high water mark and the configuration of the sides and bottom of the reservoir.

SIXTH: Surface water shall be excluded from the new reservoir. The new spring shall be walled up in masonry and covered over and protected from contamination and the water from it shall be piped into the storage reservoir. In this manner the quality of the water should be equal to that now supplied to the village.

If the company purposes to make a storage reservoir for surface water, then ample provision must be made for conducting all the drainage from around the house and immediate vicinity to below the dam, and detail plans of all this improvement shall be submitted to and approved by the Commissioner of Health before the work is done.

SEVENTH: If at any time the water works system or the source of supply or any part therefor shall in the opinion of the Commissioner of Health have become a menace or prejudicial to the public health, then such remedial measures shall be adopted as the Commissioner of Health may demand, suggest or approve.

EIGHTH: The water company shall cause monthly inspections to be made of the watersheds above its source of supply, and any change thereon from existing conditions, such as the erection of any new buildings or the removal of timber or other operation, shall be reported immediately to the Commissioner of Health. Whenever required, detail reports of the operation of the water works system shall be kept on blank forms satisfactory to the Commissioner of Health and copies of the same shall be filed with the said Commissioner.

Harrisburg, Pa., September 2nd, 1908.

BIGLERVILLE BOROUGH, ADAMS COUNTY.

Biglerville Water Company.

This application was made by the Biglerville Water Company, of Biglerville borough, Adams county, and is for permission to install a system of public water works and to obtain a source of supply therefor.

It appears that the borough of Biglerville, with a population of four hundred, comprises a manufacturing and farming community in Adams county, seven miles north of Gettysburg on the Gettysburg and Harrisburg Branch of the Philadelphia and Reading Railway. The borough was incorporated from Butler township in nineteen hundred and three and has an area of three hundred and seventy-three acres. In nineteen hundred the town had a population of about two hundred and eighty. Besides farming in the vicinity, there are half a dozen small manufacturing plants in the borough, including a canning factory and apple evaporating works.

There is no flowing water in the vicinity other than a small tributary of the Conewago Creek, which rises northwest of Biglerville. There are no sewers in the town. Of the eighty houses in the borough, six are reported to have cesspools and the remainder shallow privy vaults as the only means of sewage disposal. Wash water, garbage, etc., are generally thrown on the ground.

Water for domestic purposes is obtained principally from individual drilled wells, about fifty feet deep. There are also in the borough, six dug wells and six cisterns, so it is reported. In spite of these conditions, typhoid fever has been of rare occurrence.

The Biglerville Water Company was chartered September fifth, nineteen hundred and eight for the purpose of supplying water to the inhabitants of the borough of Biglerville.

The water company has already constructed a reservoir on Yellow Hill, one mile northwest of the borough in Butler township. This reservoir if formed by a concrete breast seventy-eight feet long across a natural ravine. The sides of the reservoir are rip-rapped on a one to one inside slope, and extend above the natural surface of the ground, thus preventing the run-off from the immediate vicinity entering the reservoir. The basin has an elevation above Biglerville of about one hundred and twenty-two feet, a capacity of about two hundred thousand gallons, and when it is full the water has a depth of six feet and a surface area of about forty-seven hundred square feet. Through the concrete breast there are two six-inch cast-iron pipes, flush with the bottom of the reservoir, one for draining it and the other being the six-inch gravity supply main to Biglerville.

A six-inch gravity main has already been constructed from the reservoir southeasterly through private property, a distance of about thirty-nine hundred feet, to the western borough line, whence the six-inch main extends easterly through the main street of the borough, a distance of about one mile. In the western part of the borough a four-inch lateral extends from the main five hundred feet south in Penn Street. A four-inch lateral is also in process of construction in the central part of the town, in Gettysburg Street, about seven hundred feet south and one thousand feet north from the six-inch main. There will thus be four dead ends in the borough.

The source of supply to the reservoir comprises three small springs. One of these is located thirty feet from the reservoir in the western slope of the ravine in which the basin lies. This spring is completely walled and covered by a masonry structure, and its water flows through a three-inch terra cotta pipe directly into the reservoir. The slope above the spring is cultivated and contains no habitation, the buildings of the farm to which this area belongs being located beyond the crest of the hill.

The second spring is located on the land of John Funt in the head of the ravine about one-quarter of a mile north of the reservoir. This spring is in a dilapidated and roofless spring-house, long since abandoned, and the water flows from it through an open and natural channel to the reservoir. About one hundred feet to the north of this spring, on the slope above it, is the residence of John Funt. In the vicinity are the barn and barnyard and an overflowing privy. The slope above the spring and the sides of the ravine above the run are largely under cultivation, although there is some woodland on the eastern slope.

The third spring is located on the land of Edward Lauver at the foot of the western slope of the ravine midway between the Funt spring and the reservoir. The water flows through an open channel to the run from the Funt spring. This third spring is in boggy ground and is not protected in any way. As already indicated, the slope above it is under cultivation.

The total drainage area above the spring is one hundred acres and contains the one farmstead mentioned. The flow of the three springs is reported to have measured sixty thousand gallons per day in July and August, nineteen hundred and eight. On Septembear fourteenth, nineteen hundred and eight, the flow appeared to be somewhat less than this. The flow from the Funt spring is probably more than the combined flow of the other two springs.

It is expected that the water system will have forty house connections to it at once and probably most of the forty remaining houses in the near future. It is also probable that the Reading Railway Company may, before long, obtain water from the water company for its locomotives. The local industries have their own drilled wells and will probably continue to use them. Fire plugs have been installed on the distributing system.

The domestic water supply obtained from shallow wells in the vicinity of loose privy vaults and cesspools and where waste water is allowed to run over the surface of the ground is suspicious. Therefore, the furnishing of a sufficient supply of pure water from outside of the borough is desirable.

The proposed supply will probably be sufficient for some time to come, but it is doubtful whether the two smaller springs, without the Funt spring, would be sufficient to meet the demands of the prospective patrons of the water company. The location of the Funt spring and of the open run from it to the reservoir immediately below the farm buildings mentioned is extremely objectionable. All the springs should be completely enclosed to prevent any possible contamination reaching them, and the water should be piped from them to the reservoir. The run-off from above the reservoir, including the surface wash from around the farmstead, should be conducted around the reservoir by means of an adequate channel, provided for this purpose. Proper means should be provided for sewage disposal at the dwelling, to which end the Department will use its influence. However, it would be much more desirable for the water company to purchase this estate and raze the buildings and strip off the surface soil in the vicinity.

The capacity of the reservoir, about two hundred thousand gallons, should be sufficient to furnish fair fire protection and also to allow for the daily variation in consumption so long as the sources of supply are adequate for the town, provided care is taken in operating the system to see that the reservoir is always as nearly full as is practicable. The six-inch gravity main should furnish two or three moderate fire streams in the central part of the town, so long as the pipes remain clean and free from incrustations. At the extremities of the four-inch laterals the fire service will be less efficient.

It has been determined that the proposed water works and source of supply will not be prejudicial to the public health and a permit is hereby and herein issued therefor under the following conditions and stipulations:

FIRST: Before water is furnished to the public, the water company shall file with the State Department of Health a plan of the watershed, showing the location of all streams, highways, buildings and other possible sources of pollution; also, detailed plans of the reservoir and springs, a plan and profile of the gravity main and a plan of the distributing system, showing the location of all blow-offs, valves and the sizes of pipe. At the end of each season's work a plan showing the extensions made to the distributing system during the year and such other information as may be required, shall be filed with the State Department of Health, in order that the said Department may always be informed of the extend of the system and of its use by the public.

SECOND: Before water is supplied to the public, all the springs shall be adequately protected from surface wash and chance or malicious pollution by means of closed water-tight masonry structures. The water shall be piped from the springs directly into the reservoir. The surface run-off from the area above the reservoir shall at no time be allowed to flow into the reservoir, but shall be conveyed around it in a channel adequate to carry this flow at all times.

THIRD: The reservoir shall be effectively protected by a fence against chance or malicious pollution. A screen shall be provided in the reservoir over the inlet to the supply main and this inlet should preferably be raised somewhat above the bottom of the reservoir.

FOURTH: Since the main spring is near the Funt residence, the water company shall have a sanitary inspection made of this property every month to ascertain whether there be any existing menace to the purity of the waters of the Funt spring, and the reports of the inspection shall be filed with the Department of Health. The water company shall see that a water-tight, masonry privy vault is constructed at the Funt farmstead and that the same is properly maintained, and that other wastes from this property are disposed of in as sanitary way as possible. Any neglect on the part of any individual or owner of property on the watersheds above the springs to comply with sanitary regulations shall be promptly reported by the water company to the Commissioner of Health. The presence of any infectious diseases on the watersheds shall be promptly reported to the said Commissioner of Health.

FIFTH: The water company shall keep monthly reports of the operation of its system on blank forms satisfactory to the State Department of Health and copies thereof shall be filed with the said Department.

SIXTH: If at any time the water supply or water works or any part thereof shall be found prejudicial to the public health, such remedial measures shall be adopted as the Commissioner of Health shall approve or advise.

Harrisburg, Pa., November 23rd, 1908.

BLACKLICK TOWNSHIP, CAMBRIA COUNTY.

Nant-y-Glo Water Company,

This application was made by an association locally known as the Nant-y-Glo Water Company, formed and controlled by Montell Davis and E. C. Davis, and is for permission to install a system of water works and supply water to the citizens of Nant-y-Glo, in Jackson and Blacklick townships, Cambria county.

It appears that Nant-y-Glo, a mining village in a mining district opened within the past ten or fifteen years, is in the western part of Cambria county, ten miles northeast of Johnstown, in Blacklick and Jackson townships. It is on the Blacklick branch of the Cambria and Clearfield Division of the Pennsylvania Railroad, which connects Nant-y-Glo with Cresson on the east (on the main line of the Pennsylvania Railroad) and Indiana borough on the west. Ebensburg, the county seat of Cambria, is on the same branch, seven miles to the east.

The South Fork of Blacklick Creek, one of the branches of the Kiskiminetas River, separates the two townships, and with the railroad on its eastern bank divides Nant-y-Glo, about three-eighth of the town being to the east in Blacklick township and five-eighths to the east in Jackson township.

Nant-y-Glo is strictly a mining village and has a population of about one thousand. A considerable proportion, though by no means the majority of the population, is foreign. The entire town has sprung up since mining operations were started in this vicinity a decade or more ago.

The South Fork of Blacklick Creek winds from its source nine miles to the village of Nant-y-Glo, where it is joined from the south by Schuman Run, a stream about three miles long, and from the north by a small run about two miles long. The village is not built up close to the banks of the main stream on either of the runs. Twenty-four miles below Nant-y-Glo, Blacklick Creek joins with the Conemaugh to form the Kiskiminetas which enters the Allegheny just above Freeport. The country in the vicinity of Nant-y-Glo is sparsely populated, but being a new mining district, nothing definite can be said of the future.

Close to the western bank of Schuman Run on the southern outskirts of the village, is a mine of the Nant-y-Glo Coal Mining Company, of Philadelphia, which, it is said, produces three hundred to four hundred tons daily, and just south of this, Pennsylvania Mine Number fourteen, of the Pennsylvania, Beach Creek and Eastern Coal Company, of New York, from which five hundred or more tons are mined daily. Two miles north of the village, near the small run already mentioned, is the Lincoln mine of the Lincoln Coal Company, of New York, which is at present running with a small shift of men, but it is said will shortly produce three to four hundred tons daily. In the eastern part of the village and northeast of the creek, is the Ivy Hill mine of the Ivy Hill Coal Company (Barker Bros., Ebensburg), producing three hundred tons daily. All of these mines discharge mine drainage into the streams. The Ivy Hill mine drainage is said to average one hundred thousand gallons daily, based on pump rating, although the pumps have a total capacity of six hundred thousand gallons daily. The stream is markedly polluted with mine drainage. About a quarter of a mile east of Nant-y-Glo, the Springfield Coal and Coke Company is opening up a large mine. A mile or so further up the stream is a small chemical works, the output of which is said to be largely the products of the destruction of wood. It is said that this works pollutes the stream to considerable extent.

A single bridge connects the two parts of the village. That part to the northeast is on ground which rises rapidly from the creek to an elevation of about sixty-five feet. To about six houses on the lower ground water is piped in a two and a-half-inch pipe from a spring and small reservoir on the hill to the north. This spring and reservoir are reasonably well protected and are above all habitation. The spring is said to have been recently maliciously opened up to allow cattle to water there, but this dispute will probably be settled. The present applicants for a permit for a new supply are those personally interested in this supply. There are also several wells in this locality.

On the same side of the creek near the Ivy Hill coal mine are twenty-eight houses, owned by Barker Brothers. Four of these are furnished with water piped to the houses from a neighboring spring. The remaining twenty-four carry their water from four running spouts, to which it is piped from a second spring in the vicinity. Both of these springs are said to be above all habitation, and although not protected from surface water, are probably reasonably safe, except from the danger of chance or malicious pollution. The boiler supply for the Ivy Hill Coal Company is taken from a bore hole at the power plant, and is said to be satisfactory.

To the southwest of the creek and west of Schuman Run the ground rises from the valley of the run and creek to an elevation of about eighty-five feet. Here the village is laid out in four blocks, though these are not built up solid, and there are occasional houses outside of them. Forty-six frame houses in pairs, belonging to one of the coal companies, extend for one thousand feet or more south from the principal part of the village. The water supply on this side of the creek is derived from about fifteen wells (several of them dug) and five or more open springs, several of which are subject to surface pollution and drainage from houses above them.

The Pennsylvania, Beech Creek and Eastern Coal Company obtain their boiler supply from Schuman Run at a point in the outskirts of the village. The Nant-y-Glo Coal Company use the less sulphurous mine drainage in their boilers. The Pennsylvania, Beech Creek and Eastern Coal Company have in view a supply of water from one of the tributary runs further up the South Fork of Blacklick Creek. It is said, however, that they are only doing enough work on the proposition to hold their charter, and it is not known locally how extensive a supply is contemplated.

The Springfield Coal and Coke Company in connection with opening their mine will probably develop a considerable village in its vicinity, and may very likely supply the same with water.

The village consists practically entirely of small frame houses, although many of them have stone foundations. There is one hotel and there are several stores. There is neither gas nor electric lighting for either streets or houses. There are no paved streets or gutters. There is said to be only one inside closet. Practically every house has its privy. Almost all the waste water finds its way to the streams through natural water courses. Just below the bridge across the creek a slaughter-house projects over the stream, and is said to discharge its wastes into the latter and at times to be the source of extremely offensive odors.

Twelve cases of typhoid fever are reported in Nant-y-Glo in the fall of nineteen hundred and six, and investigations by Department officials indicate that the infection came from overflowing privies, the drainage of which reached wells and springs. There were ten cases or more in the village during the last half of nineteen hundred and seven.

Montell Davis and E. C. Davis, the applicants, propose to introduce a supply of water from Davis Run, a small tributary of the run entering Nant-y-Glo from the north. It is proposed to install a small intake dam, gravity main to the village, and a distributing system with fire plugs. Nothing is said of the fire service in the application, but in the correspondence this is put as one of the urgent reasons for installing the system at once.

There is no incorporated company, but it is evidently intended that the supply shall be a strictly public one. In the application it is stated that one hundred and fifty acres are to be served at once, subject to applications from citizens. Permits have been obtained from the townships to allow the laying of pipes, and an agreements has been drawn up with those owners whose properties are crossed by the various pipe lines. This agreement reads in part as follows:

> "That we, the undesigned, all parties of the first part, and Montell Davis and Everett C. Davis, parties of the second part, ————
>
> "It being fully understood, however, that the said pipe line is to be used by the said parties of the second part for the purpose of the water main to supply water to the citizens of the village of Nant-y-Glo and the various districts surrounding said village or lying adjacent hereto, and for no other purpose ————————."

Thus it appears that a public supply is contemplated should the source prove adequate, and also that persons not included in the agreement may be refused the right to connect with the public system.

The area of the watershed of the proposed supply above the proposed intake is stated as one hundred and sixty-six acres, or twenty-six hundredths square miles. The territory is said to be entirely uninhabited. It is traversed by perhaps a half mile of road, which leads from Nant-y-Glo to a solitary habitation beyond the watershed, to which place there is access from another direction as well. This road crosses the stream at least once. Practically the entire area is wooded, and it is said that all of it has been timbered within the last fifteen years. A large part of the area is covered with a scrub growth.

Much of the ground is covered entirely with large rocks approaching boulders in size. Clay was also very evident in places.

Assuming a minimum rainfall of five-tenths of an inch per month, the average daily fall would be seventy-five thousand gallons on a quarter square mile and a run-off of fifty per cent. would give an average stream flow of thirty-seven thousand gallons per day. Probably reliable records of rainfall kept at Johnstown show the precipitation for October to have been forty-eight hundredths inches in eighteen hundred and eighty-seven and thirty-hundredths inches in eighteen hundred and eighty-eight, these being the only two months in twenty-six years over a period of thirty-nine years in which the precipitation fell below seven-tenths of an inch. From the character of the watershed, it would seem that there should be a very considerable natural ground storage, but whether this would be sufficient to maintain the assumed minimum stream flow throughout the period affected by a thirty-day

period of minimum rainfall or to maintain a greater daily flow throughout a longer period on which the average rainfall would be considerably greater (over two inches precipitation in sixty days, including October, in either of the two years already mentioned) is a question to be determined only by a series of stream gaugings, such as have not been made on the stream in question.

On September twenty-seventh, previous to which weather conditions had been normal, the watershed seemed rather wet. On the morning of September twenty-eighth, the head of water on an eight-inch weir was about three inches, which reduces to one hundred and sixty-two thousand gallons daily. From all reports, October is usually in the driest part of the year in Cambria county, although the present year has been a wet one. The petitioners claim that they have watched the stream carefully during the past summer and at no time in this period or in some ten years past, during which they have frequently observed it casually, has the flow of this stream been appreciably less than at the time of the Department's investigation. This is, of course, meager data as to the quantity of water when there is considerable doubt as to its being a sufficient supply.

Just below the site of the proposed intake another small run joins the run intended to be used, from the west. This second run has a watershed of, perhaps, one-third the area of the proposed supply. In case of necessity, it might be used to increase the supply, either by placing the intake below the junction or by having an intake on each run and joining the pipes. While but little head would be lost by the first method, every available foot of head will be required for an adequate fire service. A public mountain road traverses the side hill above this run.

According to the application, the intake dam proposed will have a capacity of about twenty thousand gallons. Assuming that the proposed flow of the stream would be sufficient for domestic purposes, it is very evident, however, that for fire service storage must be relied upon entirely, Therefore, unless a distributing reservoir of one hundred and fifty thousand gallons or more capacity be constructed near Nant-y-Glo the dam at the intake should certainly have such a capacity, or greater.

A dam of very much greater capacity, such as might be built to supply the ordinary daily demand during a dry spell of several weeks, could not be built at the proposed intake site without much excavation, or else a large embankment for one side of the dam as well as a breast across the valley. Moreover, were the waters of the stream backed very far above the proposed dam site, property above that owned by the applicants would be flooded, which would be undesirable whether it would cause trouble at the present or not. As already mentioned, to locate the dam even one hundred feet or so further down stream would mean the loss of head in town for fire, and here also the same objections hold as to the practicability of constructing a storage dam.

Judging from the surface, any excavation in the vicinity of the intake site would be almost entirely in rock.

The small concrete reservoir (capacity about ten thousand gallons) on the hill north of the village in Blacklick township and already referred to as furnishing water to the applicants and several parties in the lower part of the village, is fed by a small spring in the vicinity, and the supply is carried to the consumers in a two and a-half-inch pipe. The applicants own the ground around this spring and reservoir and a considerable interest in its development. They state that they intend to run the pipe from the new supply up onto the hill and connect it with the two and a-half-inch pipe near the present reservoir, cutting out the latter entirely. The two and a-half-inch pipe,it is hoped, will have a sufficient capacity for the present. This present reservoir is about thirty-five feet below the hydraulic gradient for a fire service flow in the proposed pipe line.

A distributing reservoir might be built at no great distance up on the hillside about on the steepest hydraulic gradient for the pipe proposed at present. Such a reservoir, if built at some time in the future, would, with an adequate distributing system, insure fire protection and reduce the ordinary pressure on house connections and fixtures.

Probably for the present the stream flow would be sufficient for domestic purposes and a small dam at the intake for a fire service. If the future demand exceed the supply available here, probably other runs in the same valley could be developed instead of providing storage on the present run, or by buying more property such storage could be provided, which would probably be more desirable, since there would be a smaller watershed to be kept free from pollution. Were other streams developed without building storage reservoirs, probably the most satisfaction would result from building a large distributing reservoir near Nant-y-Glo, which would also obviate the necessity of increasing the size of the gravity main in the valley for some time.

The supply main proposed is to consist of about forty-four hundred feet of six-inch pipe. There is to be two thousand feet of existing two and a-half-inch pipe incorporated in the system, merging the supply main into the distributing system. The distributing system is to consist of eleven hundred feet of six-inch pipe from the lower end of the two and a-half-inch pipe crossing the creek and in Roberts Street to corner of Roberts and Caroline Streets, and of twenty-nine hundred feet of four-inch pipe in Lloyd and Caroline Streets and in the central North and South Streets. It is proposed that at some time in the future a six-inch main be laid connecting the six-inch pipe from the intake where it joins the two and a-half-inch pipe, straight

across the valley of the South Fork of Blacklick Creek, with the distributing main in the western part of Roberts Street. Then the two and a-half-inch pipe would remain in service for distribution, but would no longer carry the entire flow.

The applicants are considering seriously using spiral riveted pipe, at least for the gravity main.

The fire protection which would be furnished by six-inch gravity and distributing mains would be poor. Eight-inch pipes would give very much better service. The six-inch pipe has not been definitely decided upon.

In order to connect with the two and a-half-inch pipe at the reservoir, the gravity main would leave the public road and be carried up on the hill. If continued in the future as proposed, to the western part of Roberts Street, this would be about the shortest route to the latter point. This arrangement would have the following advantages: First, the time required for, and the first cost of the installation of the system would be somewhat less owing to the use of the present two and a-half-inch pipe; second, the pipe lines from the point on the hill to different parts of the distributing system would be somewhat of a safeguard against breaks; third, the gravity main would be near a site for a possible future distributing reservoir.

On the other hand, if the gravity main were continued in the public road and connected to the six-inch distributing main where it was proposed to connect the latter to the lower end of the two and a-half-inch pipe, the gravity main would be on a more nearly uniform grade and the full capacity of the system would be realized from the beginning. The lower end of the two and a-half-inch pipe could be connected with such a main as part of the distributing system and, if desirable, the connection with the present reservoir on the hill could be retained in case of emergencies or heavy demand on the system, a check-valve being placed at the reservoir.

From the intake to the reservoir on the hill would take forty-four hundred feet of pipe, and from here to Roberts Street two thousand feet, making sixty-four hundred feet. From the intake to the distributing main (six-inch) in the eastern part of the village, would take sixty-two hundred feet.

The proposed distributing system would probably be considerably improved both with regard to circulation and fire protection, by increasing the four-inch pipe in the principal North and South Streets to six inches, or eight inches from Roberts Street to Davis Street, and connecting it at the latter point by four-inch pipe in Davis Street to the four-inch laterals in Caroline Street and Lloyd Street.

With these suggestions, the distributing system would consist of eighteen hundred feet of six-inch pipe and twenty-nine hundred feet of four-inch pipe. The western three hundred feet in Roberts Street might be reduced to four inches, but this would not be desirable if the proposed six-inch pipe from near the present reservoir on the hill is to intersect Roberts Street at its western end.

To summarize, it appears that it is desirable that a domestic water supply and fire protection system of water works should be installed. The petitioners are willing to build the system proposed for their own particular benefit and for the benefit of others.

A very considerable part of the town consists of houses owned by the different coal companies, many of which are already supplied with water. Moreover, it seems that a considerable part of the future growth will consist of mine employes who will probably live in houses to be built by an additional mining company and some perhaps by the present companies. Therefore, the introduction of water being a private enterprise, naturally for the purpose of earning a profit, it is not to be expected that the applicants will spend more money on the project than reasonably sure profits warrant.

The springs and wells which are the present sources of water supply are evidently unfit for domestic use, and a pure supply of water would be in the interests of public health.

From all available information it seems that the proposed source of supply will be reasonably pure.

While the quantity is small, it will in all probability be adequate for the domestic consumption for a few years and may be for a much longer time. It is also possible to provide a fairly satisfactory fire protection. This, however, and the augmenting of the supply in the future are questions to be considered in detail by the water company. The sizes of pipes have been discussed, but these also must be finally decided upon by the applicants.

It has been determined that the proposed water works system and the source of supply will not be prejudicial to public health, and a permit is hereby and herein granted therefor to the Nant-Y-Glo Water Company, under the following conditions and stipulations:

FIRST: That ample facilities shall be provided for draining both the gravity main and the distributing system and also the intake dam or reservoir.

SECOND: If at any time it is found desirable or necessary to include the present spring or reservoir hereinbefore mentioned in the proposed system, said spring or reservoir shall be adequately protected from surface drainage or chance pollution and facilities shall be provided for draining them. Plans of said spring and reservoir and their connections to the proposed system shall be filed with the Commissioner of Health.

THIRD: Complete plans of the intake arrangement for the proposed supply and complete plans for the proposed distributing system as installed and plans showing the location of all blow-off outlets shall be filed with the Commissioner of Health.

FOURTH: If at any time in the opinion of the Commissioner of Health the water works system or the source of supply or any part thereof shall become prejudicial to the interests of the public health, then such remedial measures shall be adopted as the Commissioner of Health may demand, advise or approve.

FIFTH: No additions to the system or supply shall be made without application to and approval by the Commissioner of Health. At the close of each season's work a plan of the water pipes laid in the streets of the town during the year, showing the sizes, gates and blow-offs, shall be prepared and filed in the office of the Commissioner of Health, together with any other information in connection therewith that may be required, to the end that the Department of Health may always be informed as to the extent of the water works system and its use.

SIXTH: If any lumber operations should be undertaken on the watershed or any habitation or source of pollution be established thereon at any time, the Nant-Y-Glo Water Company, so called, shall immediately notify the Commissioner of Health thereof and co-operate with the Department of Health in the enforcement of sanitary regulations to safeguard the water used by said company as a source of supply to the public.

Harrisburg, Pa., August 15th, 1908.

BLOSSBURG BOROUGH, TIOGA COUNTY.

This application was made by the Blossburg Water Company, of the borough of Blossburg, Tioga County, Pennsylvania, and is for permission to introduce an additional source of supply of water to the public in said borough.

It appears that Blossburg borough is a community of about twenty-eight hundred population, located in the southeastern portion of Tioga County near the headwaters of Tioga River, a stream which flows northerly into the State of New York and empties into the Chemung River, a tributary of the North Branch of the Susquehanna River. The municipal territory, which is about two and a half miles square, is bounded on the north by Covington Township, on the east and and south by Hamilton Township and on the west by Bloss Township. About four miles to the east is the borough of Fallbrook, through part of which Tioga River flows easterly and passing through Hamilton Township enters the southeastern corner of Blossburg borough and thence pursues its course northerly about midway of the incorporated area. The village is built along the east bank of the stream. The houses are well scattered, the streets are unpaved and there is no sewer system, but a few private sewers empty directly into the stream. The principal industry is the tannery plant of the United States Leather Company. A branch of the Erie Railroad, Tioga Division, follows up the east bank of the river to Blossburg and thence it forks, one branch extending westerly up the valley of Johnson's Creek and another branch extending easterly up the river of Fallbrook to Fallbrook borough. There are coal mines in these valleys.

The surrounding territory is hilly. The customary methods of disposal of house sewage prevail in the absence of sewers. There are probably one hundred and fifty domestic wells in use, mostly in the higher portions of the village. According to reports, typhoid fever has not been prevalent.

The original water works plant was installed by the Blossburg Water Company about eighteen years ago. At the present time the Company supplies four hundred and twenty-five out of six hundred dwellings. It also furnishes water to the tannery and to the Erie Railroad Company. Fire protection is afforded by the system and the pressure in the lower part of the town is said to be one hundred pounds. The following description of its source of water supply was submitted by the water company on August twenty-first, nineteen hundred and five:

"The supply of water to the Blossburg Water Company is derived from Taylor Run, a mountain stream, emptying into the Tioga River two miles south of Blossburg borough.

"The reservoir which has a capacity of 3,000,000 gallons is located three-fourths miles from the mouth of the stream, one thousand five hundred and seventy-six feet above tide water or two hundred and twenty-eight feet above the borough. The water is delivered to the said borough through a ten and eight inch main. The line has two intakes one in the stream above storage and the other in the storage, the stream however furnishes a supply adequate to meet the demands of the consumers and the storage is drawn upon only during a very short period each year.

"The said stream runs through a sandstone formation two and one-fourth miles to the reservoir and fed entirely by springs. The entire watershed is covered by hard wood mostly Beach, Birch and Maple. The Water Company are the owners of a large portion of the watershed. The water is entirely free from any contamination, there being no residences, barns or other buildings of any description in the territory drained by the stream."

From the Department's inspection it appears that the Taylor Run reservoir has a capacity of about three million gallons, is timber cribbed, rock filled breast with planked face. The reservoir is apparently in good condition with dry rubble

wall around about two-thirds of the circumference. The water is clear and in the deep part has the dark color of water from a timbered watershed. The reservoir has a sluice gate for emptying, with sluice trough through the center for cleaning, which operation is carried out once in three years.

The watershed is approximately three square miles in extent. It is uninhabited and covered entirely with second growth timber about ten years old. Sub-soil is sandstone, rock and gravel. One or two mountain roads pass through the shed but have very light travel. The supply main from old reservoir on Taylor Run is about twelve thousand feet in length, is eight inch iron pipe provided with blow-offs for cleaning.

There is no growth in the water of the reservoir and nothing could be noted in either taste or odor.

The water pipe system in the village comprises about one-quarter of a mile of ten inch cast iron pipe, three and one-half miles of eight inch, two and one-half miles of six inch, two miles of four inch and about three-quarters of a mile of two inch pipe.

Taylor Run is a tributary of Tioga River and it enters the same near Hamilton Township near the borough line. The stream rises in Liberty Township to the south and the source is not always sufficient.

In order to make up for lack of water in dry seasons, a horizontal duplex Buffalo pump, five inch suction, four inch discharge, operated by steam, was installed on Tioga Creek at the junction with Taylor Run. This pump has been operated about one month in each year, but the water supplied by it from Tioga Creek is open to suspicion as it includes drainage from an old mine workings, now abandoned containing more or less sulphur. Tioga River here also receives drainage from bark extract works and from Fallbrook habitations. The water company, appreciating that this condition is not all that it should be, purposes to move the pump about one-half mile up stream on Taylor Run where it will catch the overflow and leakage from the old reservoir. It is expected, however, that with the supply from the new reservoir, this pump will not be used for some time to come. When the pump is operated, it pumps directly into the supply lines.

In making an application for approval of the new source, the Blossburg Water Company submits the following statement:

"The Company files herewith a map showing the plans, surveys and water works of the Company as existing at the present time, together with a description showing the sources of water supply.

"The supply of water from Taylor Run was not sufficient for the requirements of the Company. In order to provide a sufficient supply of water it became necessary for the Company to use the water of Bellman Run.

"The Company began the construction of the reservoir and pipe line required for the use of water from Bellman Run on July 7, 1907. The work was completed about June 1st, 1908. The water has been turned into the line for the purpose of testing the pipe. It has not been used for domestic purposes.

"The omission of the Company to apply for a permit was not due to any intention to evade the law, but was due solely to the fact that the officers of the Company overlooked the Act of April 22nd, 1905."

Bellman Run is a tributary of Johnson Creek. It has several branches and its watershed of about six square miles lies partly in Bloss Township and partly in Hamilton Township, south of Johnson Creek and the Erie Railroad.

An additional statement by the Company in reference to the source of supply is as follows:

"I herewith submit for filing in your department a Blue Print of a complete map of the pipe lines and watershed of the Blossburg Water Company. The watershed from which the supply is derived is about 1,800 feet above tide, well timbered with Beech, Birch, Maple and some soft woods. There are no dwellings or any other thing to contaminate the supply. In fact the watershed is timber lands uninhabited. The land formation is of sandstone and the points where the supply is taken are well above the coal measures.

"The reservoir on Taylor Run and Bellman Run are located on the respective streams. Taylor Run reservoir has a capacity of two million eight hundred and thirty thousand gallons and Bellman Run reservoir a capacity of one hundred and twenty-four thousand gallons with overflows. The subsoil has been removed from both reservoirs, leaving a gravel bottom, the sides are protected with stone walls. The intake at both reservoirs are protected by a screen three feet square perforated with three sixteenth of an inch holes and thoroughly covered with three feet of gravel and broken stone. The Taylor Run reservoir is located about two hundred and twenty-seven feet above the Borough, the delivery is made with an eight inch line. Bellman Run reservoir is located two hundred and forty-five feet above the Borough, the delivery is made with a six inch line. Bellman Run line joins the Taylor Run line at the intersection of Tabor Street and Williamson Road near the tannery shown on the map.

Respectfully yours,

THE BLOSSBURG WATER COMPANY,

F. H. Stratton, Supt."

The Department has ascertained by investigation that the additional water supply is required and has been provided for, as stated, in the reservoir on Bellman Run, whose construction is similar to the Taylor reservoir and whose elevation is about twenty feet higher than the Taylor reservoir. The six inch cast iron supply main about fourteen hundred and fifty feet long extending down the valley in Williamson Road, paralleling the Erie Railroad, is completed, and ready for use. The same general conditions obtain and the same statements may be made with regard to the new supply that have been herein made relative to the old supply. Negotiations are on foot for complete ownership and control by the water company of the new watershed.

It has been determined that the water works and proposed additional source of supply will not be prejudicial to public health and a permit is hereby and herein granted therefor, under the following conditions and stipulations:

FIRST: The water company shall not pump any water from the Tioga River in to the water district. Before any change of location of the pump house or plan is made, complete plans thereof shall be submitted to the Commissioner of Health for approval.

SECOND: Detail plans of the reservoirs and dams, gates, drains and pipes and valves location shall be prepared and filed with the Commissioner of Health on or before January first, nineteen hundred and nine. At the close of each season's work the water company shall make a plan of the water pipes laid in the streets of the borough during the year and file the same in the office of the Commissioner of Health, together with any other information that may be required in the operation thereof, in order that the State Department of Health may always be informed of the extent of the water works system and the public use thereof.

THIRD: If at any time, in the opinion of the Commissioner of Health, the water works system or the source of supply has become prejudicial to public health, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

FOURTH: It is the intention of the Commissioner of Health to make tests of the source of supply from time to time and the water company shall assist in such examinations, if required. Records of the operation of the system shall be kept on blank forms from the State Department of Health and copies thereof submitted, if asked for.

FIFTH: The company shall designate on a map to be prepared of the water pipes in the streets of the borough and filed in the office of the Commissioner of Health on or before January first, nineteen hundred and nine, the size of all water pipes, the location of gates and drainage facilities. And, if it shall appear that such drainage facilities are not adequate, then the water company on request of the Commissioner of Health shall improve such facilities to the Commissioner of Health's satisfaction.

SIXTH: It is especially stipulated that this permit is issued with the understanding that the watershed is uninhabited. If at any time any dwellings or occupations or permanent sources of pollution should be established on these areas tributary to these reservoirs, then the Commissioner of Health shall be amply notified beforehand and he will issue and put in force such regulation as shall safeguard the sources of supply from sewage pollution.

Harrisburg, Pa., July 21st, 1908.

BRADFORD TOWNSHIP, McKEAN COUNTY.

South Bradford Water Company.

This application was made by the South Bradford Water Company, of Bradford Township, McKean County, and is for permission to extend water works for the supply of water to the public in the village of South Bradford, Bradford Township, McKean County.

It appears that the South Bradford Water Company was chartered September twenty-third, nineteen hundred and one, for the purpose of supplying with water for domestic and manufacturing purposes the inhabitants of that portion of Bradford Township, McKean County, lying south of the south line of Bradford City west of the public highway leading from Bradford City south to Misard Run Road on the east side of the Tunungawant Creek, north of the road leading from the village of DeGolia up Misard Run and east of the dividing range of hills lying between the east and west branch of Tunungawant Creek, comprising an area of about two square miles.

At the time of the incorporation of the water company the principal stockholder, James W. Leasure, had arranged to supply running water to the green houses and caretaker's residence of his farm to these places only, but on request of adjoining property owners in the neighborhood he decided to form a company and he has since been furnishing four other properties besides his own with water.

The source is a spring located on the side of the hill west of the water district about two thousand feet west of the east branch of the Tunungawant Creek and elevated about two hundred and fifty feet above the valley. The ground west of the spring continues to rise to the summit of the range which divides the east and west branches of Tunungawant Creek.

About midway on the slope from this range to the east branch is the main highway leading south from the city of Bradford. The water works and source of supply are west and above this thoroughfare. The elevation of the spring is in the neighborhood of one hundred and fifty feet above the road. The land around the spring is wooded and there are no buildings of any kind on the slope above. The land is all owned by Mr. Leasure to the summit.

The spring at present is uncovered, but is surrounded by a loose stone wall which retains the excavation, which is about two feet square, from which the water flows out from the shale rock and passes away down the mountain brook. The measured flow is stated to be three hundred thousand gallons each twenty-four hours. A one and a half inch wrought iron pipe leads from the spring a distance of six hundred feet to an uncovered wooden tank ten feet in diameter and ten feet high. A two inch supply main leads from this storage tank to the green-houses which are distant about two hundred feet and about fifty feet lower than the tank. A one inch supply pipe is taken off the two inch main and extends to the caretaker's residence. This one inch pipe also extends across the highway to four other dwellings in the neighborhood. The total population being supplied at the time of the Department's inspection in nineteen hundred and seven was twenty people. There are about one hundred families residing in the charter territory of the South Bradford Water Company. It is evident, therefore, that the quality of water available is ample based on the above measurement.

The petitioners' purpose to replace the loose stone retaining wall about the spring by a tight concrete wall so as to make it a receiving basin four feet square. This is to be roofed over and securely guarded.

Two hundred and fifty feet away from the spring has been constructed a new storage reservoir thirty-eight feet long and thirty-two feet wide and four feet deep. Its sides are of stone masonry and the foundations are concrete. A double line of one and a half inch pipe connects the spring with the storage basin.

A new four inch supply main extends from the reservoir to the green-houses from whence a three inch distributing pipe leads to the highway and a two inch pipe has been laid along the road.

At the date of the Department's inspection the changes had been practically completed.

Should it be desirable to further increase the source of supply in order to admit of the extension of the water pipes to other parts of the water district and to furnish all of the inhabitants with drinking water, it is reported that there are other springs on the farm owned by Mr. Leasure which may be easily incorporated into the system.

It has been determined that the proposed source of supply is not prejudicial to public health and the same is hereby and herein approved, as well as the water works extension, under the following conditions and stipulations:

FIRST: That the walls surrounding the spring and source of supply be constructed and the roof be put on and kept securely locked as proposed and that the water company shall provide a drainage ditch around the upper sides of the spring to carry away all surface water, that over the ends of the supply pipes leading from the spring shall be placed screens and that gates or valves shall be placed on these pipes to admit of the water being shut off if necessary. There shall be an overflow pipe placed in the upper portion of the wall at the spring, provided with an elbow and a screen over the vertical pipe.

SECOND: Ample overflow and drainage pipes and screens at inlet and outlet pipes shall be provided at the storage reservoir. Also valves on pipes to admit of the shutting off of the water or drainage of the basin. A high tight board fence shall be constructed around the reservoir to prevent accidental or malicious pollution of the water. The water company shall properly intercept all surface water so as to absolutely prevent any of it reaching the reservoir.

THIRD: That before any additional spring supply be made plans shall be prepared thereof and submitted to the Commissioner of Health for approval, and that if at any time the water supply or the water works system or any part thereof shall become prejudicial to public health in the opinion of the Commissioner of Health, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

Harrisburg, Pa., May 5th, 1908.

CATASAUQUA, LEHIGH COUNTY.

This application was made by the borough of Catasauqua, Lehigh County, and is for permission to drill wells, and install a system of public water works, and for investigation by the State Health Department and approval of sites for a proposed drilled well supply and water works system.

The borough of Catasauqua is a long established manufacturing town, located in the eastern part of Lehigh County, on the eastern bank of the Lehigh River, two miles north of Allentown. It is on the suburban outskirts of the district

recently occupied, as a result of the adaptability of the natural rock, by numerous large cement manufactories. This industry together with iron works and silk mills furnishes employment to most of the inhabitants of Catasauqua, and the community of which it is a part and which stretches up both banks of the river for a distance of six miles from Allentown. Catasaqua had a population of thirty-seven hundred and four in eighteen hundred and ninety; thirty-nine hundred and sixty-three in nineteen hundred and four thousand or more in nineteen hundred and eight.

The borough has an area of about a half square mile, triangular in shape, and is bounded on the north by North Catasauqua borough, Northampton County, on the west by the Lehigh River and on the east by Hanover Township, Lehigh County and Catasauqua Creek, which flows southerly to its confluence with the river at the southern end of Catasauqua. The canal of the Lehigh Coal and Navigation Company follows the bank of the Lehigh River through the borough, the tracks of the Central Railroad of New Jersey lying between the two water ways. The canal branches from the river at a dam across the latter about two thousand feet above the borough. The Crane Iron Works of the Empire Steel and Iron Company are located on the east bank of the canal near the central part of the borough and to a very considerable extent make use of the waters of the canal for power purposes, the level of the canal being lowered five or six feet in a lock at the site of the Crane Iron Works.

Between the river and Catasauqua Creek the ground of the borough rises rapidly to an elevation above Front Street, along the canal, of about ninety feet at the northern borough line. The surface drainage, including considerable domestic waste water drained to the gutters, is conveyed, in some cases by storm drains and culverts, to the canal and the creek. Privies are very generally in use throughout the borough and the custom prevails of disposing of much of the domestic sewage into crevices in the limestone formation underlying the borough. There are springs in the limestone rock both along the canal and the creek, particularly in the southern part of the borough. Some of these have been condemned by the local authorities as sources of supply for drinking water. The dug wells at one time very generally in use, are said to have become polluted and been abandoned almost without exception. On perhaps half the properties within the borough rain water cisterns are in use.

Catasauqua, incorporated as a borough in eighteen hundred and fifty-three, was, it is reported, supplied for a time by a Crane Water Company; and later, about eighteen hundred and fifty-seven, by the Lehigh Crane Iron Company. The Crane Water Company, incorporated in eighteen hundred and ninety-five, and the Clear Springs Water Company, incorporated in eighteen hundred and ninety-nine under the laws of the Commonwealth, supplied water to the public in Catasauqua until about the end of nineteen hundred and two. Seven water companies supplying water in the vicinity, including the Crane Water Company and the Clear Springs Water Company, were merged under the laws of the Commonwealth into the Clear Springs Water Company, to which letters patent were issued April tenth, nineteen hundred and two, for the purpose of supplying water to the public within the charter territories of the original companies, which include all of Lehigh and Northampton counties. This water company since nineteen hundred and two has furnished water for the public and fire protection in Catasauqua.

The Clear Springs Water Company pumping station number two is located in the borough in the southern part of the Crane Iron Works near the canal. There is a drilled well adjacent to the pumping station which is said to be about two hundred and fifty feet deep and is one hundred feet or more from the canal. Water is forced from this well by means of compressed air into a small pump well. There is also about a ten inch intake pipe leading from the head race of the Crane Iron Works to the pumping station. This head race branches from the canal immediately above the lock and passes through the Crane Iron Works furnishing water for power purposes. The two pumps of the water company are connected so that by the operation of valves either pump may be made to take its supply either from the intake furnishing canal water or from the pump well supplied with well water. The discharge pipes unite in a twelve inch rising main in which the water passed to a standpipe near the pumping station, about five feet in diameter, installed for the purpose of relieving the distributing system of the jar from the pumps. From this standpipe the water passes through the distributing system and overflows into about a five hundred thousand gallon standpipe located on the high ground in the extreme northern part of the borough. On July eighteenth, the pumps were operating at about equal speeds, the western one pumping canal water, the eastern one well water, so that apparently about half the supply furnished directly to the consumers was being obtained from the Lehigh canal. Above the head race intake from the canal the latter receives considerable surface drainage from Catasauqua and North Catasauqua. Within a mile above the intake on the low lying canal banks are the privies of a number of dilapidated frame dwellings and vaults in the limestone rock receiving the sewage of the employes of a planing mill in Catasauqua and the sewage of the employes of the Bryden Horse Shoe Company in North Catasauqua, the vault of the latter being about two hundred feet from the canal, that of the former about one hundred feet. The Lehigh River above the entrance of the canal at the dam receives drainage and sewage from White Haven borough and from Mauch Chunk

and East Mauch Chunk, twenty-two miles above Catasauqua, and below Mauch Chunk, from Lehighton, Parryville, Slatington, Alliance, Coplay and other places. The river also receives large quantities of mine drainage in Sandy Run and Black Creek from the anthracite coal fields near Hazleton.

The distributing system of the water company in Catasauqua comprises more than six miles of pipes ranging from four to ten inches in diameter. Plugs are rented by the borough for fire protection. It is said that only about half of the inhabitants use the water, the remainder being dependent principally upon rain water cisterns. The methods of the water company are said to be generally unsatisfactory to the citizens.

At several points along the northern borough line the distributing system is connected with that of the same water company in North Catasauqua. It is said that ordinarily valves on these connctions are kept closed, but that during the trouble at the Catasauqua pumping station these valves may be and have been opened so that Catasauqua at times receives its supply from the other source of the Clear Springs Water Company.

This other source of supply is obtained from Spring Creek, also called Mill Creek. There is an impounding dam of about one hundred million gallons capacity on this creek in the extreme northern part of Whitehall Township, Lehigh County, and about a quarter of a mile from the river. Spring Creek, above the dam, has a largely cultivated watershed of about three square miles in Whitehall and North Whitehall Townships, containing a population of two hundred and ninety. An inspection of this watershed has been made by officers of the Department and there have been served upon persons owning property on the watershed for the abatement of nuisances or menaces to the purity of the water twenty-three written notices.

The water company maintains a pumping station below the dam near the river. There is a twelve inch suction pipe from the dam and an auxiliary twelve inch suction from the river. A Jeansville duplex compound condensing pumping engine forces the water through a ten inch force main about four thousand feet to a three million gallon distributing reservoir on Lincoln Heights west of the village of Cementon. From this reservoir the distributing system of the Clear Springs Water Company extends down stream along both banks of the Lehigh River for a distance of four miles or more, furnishing water on the eastern side of the river to the boroughs of Alliance and North Catasauqua in Northampton County and Catasauqua borough and East Catasauqua village in Lehigh County, and west of the river to the village of Cementon, Coplay borough, and the villages of Kokendauqua, West Catasauqua and Ferndale, all in Lehigh County. The impounding dam on Spring Creek is supplied principally, during dry weather, by a large spring in its upper end. On July seventeenth, nineteen hundred and eight, the flow of the surface stream from the valley, known as Drum Hole, was almost inconsiderable. On the same date the water in the distributing reservoir was turbid and there were numerous small dead fish floating on the surface. During October and November, nineteen hundred, a typhoid epidemic at Cementon was investigated by officers of the State Board of Health. There were reported to be at least one hundred and sixty-five cases and thirteen deaths in and around Cementon, although the cases outside of the village were but few and scattered. The evidence collected seems to indicate as the source of infection Leisenring Spring, from which the water company furnishes water to the district in Cementon where typhoid was most markedly present. The cases in the districts supplied with Spring Creek water from the distributing reservoir were attributed to the patients having visited in Cementon. However, colon bacilli were found in samples both of the Spring Creek water and of the Leisenring spring water and the existence on the Spring Creek watershed of earlier cases of typhoid to which some of the cases of the epidemic might be attributed was discovered.

Since October, nineteen hundred and five, there have been twenty-two cases of typhoid in Catasauqua borough, according to the reports made to this Department.

The Clear Springs Water Company has filed plans showing the Spring Creek impounding dam, the layouts of the two pumping stations and the lines of the distributing system. Plans are not on file in the Department showing the watershed of Spring Creek, the Lincoln Heights reservoir and the distributing system indicating the sizes of pipes and the location of blow-offs.

The borough having become dissatisfied with the quality of the water furnished by and the methods of the Clear Springs Water Company has resolved upon acquiring or installing public water works. On December twenty-eighth, nineteen hundred and seven, the borough filed a petition in the Court of Common Pleas asking the appointment of three appraisers to set a value upon the company's water works in Catasauqua as provided for in the Act of Assembly approved May thirty-first, nineteen hundred and seven. Thereupon, the water company filed with the court a disclaimer refusing to sell its plant at any price and forfeiting any exclusive privileges which it might have in the borough, as provided for in the said Act. On April twenty-seventh, nineteen hundred and eight, the court declined the petition of the borough in view of the filing of this disclaimer which has been recorded in the office of the Recorder of Deeds of the proper county and expressed the opinion that the borough was free to install its own water works and supply water to the public.

Therefore, the borough contemplates installing its own water works and a public vote will shortly be taken upon the issuing of bonds to raise money to cover the expense.

It is intended to install a drilled well or wells, pumping machinery, a standpipe and distributing system. The entire plant as proposed will be within the borough, except that the distributing system may be extended to outside consumers.

Two alternate sites are considered for the location of the proposed well. One is in the northeastern corner of the borough, just south of Walnut Street and about two hundred feet west of and twenty-five feet higher than Catasauqua Creek at this point. If this site is selected, the fuel will, for the present at least, be carted to the pumping station and the water will be pumped through a force main directly to the standpipe to be located on the high ground near the northern borough line either within the borough or in North Catasaqua borough. The other site is in the eastern part of the borough just north of Wood Street and between American Street and Catasauqua Creek. The site is within one hundred feet of the creek and about twenty feet above it and the well would extend through filled ground in the mouth of an old limestone quarry. Both well sites are considerably above the highest freshet elevation of the creek. It is said that arrangements can be made with a factory having a railroad siding across the creek from the lower well site, that last mentioned, whereby the borough will be allowed to install a mechanical conveyor to carry the coal, if this fuel is determined upon, from cars on the siding to the pumping station. In the case of the selection of this site the water will be pumped directly into the distributing system and overflow into the standpipe near the northern borough line and a standpipe of small diameter will probably be placed at the pumping station with the pumps. Whichever site is selected, it is intended to carry the well or wells if it seems advisable to build more than one to obtain the needed supply, to a depth of perhaps seven hundred feet, at which depth it is expected that water can be obtained from strata beneath the limestone.

The standpipe is to be thirty feet in diameter by seventy-five feet high, so as to have a capacity of about four hundred thousand gallons. It is intended that the pumps and well or wells shall have a capacity to furnish water at the rate of one and a half million gallons per twenty-four hours. Therefore, it seems that, with the exercise of reasonable care in the operation of the plant, a fairly satisfactory fire protection will be assured, especially as the borough has steam fire engine service. The fire service furnished by the water company is to be discontinued. No auxiliary source is to be provided. The Catasauqua Creek, having a watershed above the town of twelve square miles, would hardly furnish a source of fire supply without the installation of an impounding dam.

The distributing system as designed consists of thirty-eight thousand feet of pipe, consisting of forty-eight hundred feet of six inch pipe, twenty-seven thousand four hundred feet of six inch pipe and sixty-one hundred feet of four inch pipe. The system is well supplied with valves and is so designed as to have but few dead ends. The location of blow-offs is not indicated.

There is no reason to suppose that a satisfactory and wholesome supply may not be obtained from the proposed drilled wells. However, even though the wells are to be deep and if possible to draw from strata below the surface limestone and even though every precaution to guard the wells from surface pollution be taken, nevertheless, the underground supply from which the well or wells are to draw may at any time be polluted by the sewage of the borough disposed of in the crevices of the limestone rock or even by the sewage of neighboring communities and the borough must shoulder the responsibility for endeavoring to obtain a pure supply from the proposed source. The buildings of the town are within a few hundred feet of either well site. The general dip of the surface limestone in the neighborhood is to the south as indicated in the old quarry near the Wood Street well site and at other outcrops in the vicinity, probably, therefore, there is a little more likelihood of obtaining contaminated water from the Wood Street site than from the Walnut Street site. Moreover, the elevation of the latter is somewhat above that of the former and the distance for the water to be pumped to the standpipe will be considerably less if the well is located at the Walnut Street site.

The borough purposes to expend sixty thousand dollars for the installation of this system and it is understood that the municipality can borrow at least ninety thousand dollars

The water of the Lehigh River, polluted as it is with sulphurous mine drainage, is said to furnish an extremely unsatisfactory boiler water supply. For this purpose almost all the factories in and around Catasauqua use well or spring water. If the borough can obtain a first class domestic supply and also one suitable for boiler purposes and can supply the same at sufficiently reasonable rates, the water works may prove a good investment.

It has been determined that the proposed water works and source of supply will not be prejudicial to public health and a permit is hereby and herein issued therefor under the following conditions and stipulations:

FIRST: Ample facilities shall be provided by means of blow-offs placed at all points whereby the rising main, standpipe and supply main and distributing system may be completely drained.

SECOND: Detail plans of the lay-out at the pumping station, and of the rising main, standpipe and distributing system, showing the location of all valves, blow-offs and sizes of pipe as finally decided upon, shall be filed with and approved by the Commissioner of Health before the work is commenced on these respective parts of the system. Before water is supplied to the public from the proposed source a description and plans of the construction of the well or wells shall be filed with the Commissioner of Health.

THIRD: It is the purpose of the Department to obtain samples of water for analysis from the various parts of the system from time to time and the petioners shall render such assistance in carrying out this idea as may be necessary and shall make such alterations in the system and source of supply as the Commissioner of Health may demand, suggest or approve in the interests of public health to the end that the water supplied by the water works shall not be prejudicial to the public health.

FOURTH: Detail records of the operation of the water works shall be properly kept on blank forms to be suggested by this Department and copies thereof shall be furnished to the Commissioner of Health.

FIFTH: At the close of each season's work plans shall be prepared and filed with the Commissioner of Health showing extensions to the distributing system made during the year, so that the Commissioner of Health may always be informed of the extent of the water works and the district supplied thereby.

SIXTH: The permission herein granted is given under the express stipulation that if the distributing system is extended beyond the borough limits for the supply of water to the public the conditions of all laws pertaining to such extensions shall be complied with.

SEVENTH: It is expressly stipulated that before the water shall be introduced into the public system of the town, satisfactory chemical and bacteriological tests of the waters shall be made of enough samples taken over a period of days to thoroughly and satisfactorily prove the water to be free from all contamination.

That attention of the local authorities is called to the fact that drilling for a ground water supply, especially in limestone formation, is always more or less of a gamble. The very gist of this whole enterprise proposed is expressed in the requirements as to a test of the waters before they be used by the public.

Harrisburg, Pa., August 14th, 1908.

CHAPMAN TOWNSHIP, CLINTON COUNTY.

(Absalom Farwell).

This application was made by Absalom Farwell of Chapman township, Clinton count, Pennsylvania, and is for permission to install a system of water works for the supply of water to the public in the village of Farwell, said township.

The village of Farwell is the result of a real estate development scheme of the petitioner. Mr. Farwell was an owner of a tract of land comprising several hundred acres, located along the northern side or bank of the West Branch of the Susquehanna River about one and a half miles below the borough of Renovo and extending back to the top of the mountains which parallels the river in the region. A portion of this tract was laid out in town lots by the owner. These lots have nearly all passed to the ownership of separate individuals, some of whom have erected dwellings on the lots. The development lies between the Philadelphia and Erie Railroad and the river and thereon are eighty plots, equivalent to an approximate population of four hundred were every plot occupied by a house. It is expected that even a larger settlement may eventually result.

The crest of the mountain is six hundred and fifty feet above the river bank and back therefrom a distance of about three-fifths of a mile. The flats along the stream are about eight hundred feet wide and terminate about at the railroad. From here northerly the mountain slopes begin and at an elevation of about fifty feet above the village there is a public highway on the mountain side which is the main thoroughfare for public conveyances from Renovo to Lock Haven. The mountain side is well wooded and unoccupied.

For the convenience of the prospective villagers and to aid in the sale of house lots, Mr. Farwell constructed a system of water works during the season of nineteen hundred and six. The source of supply is five springs.

Four of the springs now supplying the plant are located along the upper side of the public highway. Each spring has been walled up with cement and stone and covered over with flagstone, the entire structure being water tight so that no pollution may be introduced to the water from the outside. None of the masonry work appears above the ground. The location of three of the springs, however, may be seen from the highway by reason of the excavation into the mountain side. The fourth place is obliterated by a landslide.

From the collecting well at each spring a one and a half inch pipe has been laid underneath the highway and finally terminating in a small collecting masonry wall at a spring below the public road and distant therefrom about one hundred and fifty feet. Adjacent to this spring which is walled up and covered similar to the others, the water is conveyed by a pipe to an adjacent storage reservoir

fifteen feet square and five feet deep. The construction of this basin is stone masonry lined with cement and made water tight. Over it is a wooden building with a door under lock and key or more properly speaking a wooden roof, there being no floor or platform provided under the roof. There is a three inch overflow pipe at the reservoir. The water is conveyed to the village by a four inch cast-iron pipe, the outlet end being raised six inches above the bottom of the reservoir. There is a valve on the line outside of the building. There is also a drain pipe.

The supply main is about one thousand feet long. It terminates in Prospect Street in the eastern part of the village. Connecting with it at the present time is a pipe line in McCloskey Alley thirteen hundred feet long, the diameter ranging from two inches to one and a half inches. Off the four inch line other street pipes are to be taken when required. One branch now leads to the farm house near the village. The object of the works is to supply drinking water only. The static head from the reservoir is not over thirty-three feet.

The minimum capacity of the springs is reported to be forty-five hundred gallons per day, which is an insufficient amount for the domestic uses of four hundred people.

There are two other springs further up the mountain side on the Farwell estate which are available from which the flow is estimated to be greater than the combined capacity of the five springs now in use. The applicant purposes to attach these new springs to the present supply and also to drill a well, or more than one if necessary, near the present reservoir, and to increase the source of supply sufficiently for the needs of all consumers.

The borough of Renovo is located on a table land hemmed in between the mountains and the river. All the available land there has been taken up, so that the increased population must seek places of residence outside of that borough. This they are doing.

There is another plot of ground adjoining Farwell village to the west upon which a settlement exists and from which a demand for water may come. It is the intention of the petitioner to extend water pipes for the supply of water to the public into this other settlement if such extension should prove advisable.

Detail plans of the reservoir have not been filed. The Department's inspection makes it evident that the water should be of excellent quality and satisfactory for domestic purposes. The situation and surroundings at the springs are such that the probability of any pollution is most remote and, in fact, seems to be almost impossible. The springs come from the shale rock, are continuous in flow, but during times of extreme drought the quantity is limited.

Additions to the supply must be made if the village grows and the demand for the water increases proportionately. The supply is preferable to that of individual wells sunk on properties and in proximity to privies and cesspools. The interests of the public health should be subserved by the extension of proper water works and the furnishing of a pure mountain water to the inhabitants of the district. The works, however, should be extensive enough to afford ample supply and proper pressure at the dwellings of the consumers. And undoubtedly fire protection will be demanded ultimately. In the extension of the works and in obtaining an additional supply of water, these things should be taken into consideration.

It has been determined that the existing sources of supply are not prejudicial to public health, and the supply and the water works system as it now exists is hereby approved and a permit granted for an additional supply and for an extension of the water works system, under the following conditions and stipulations:

FIRST: That a ditch be constructed around the existing reservoir, of sufficient depth to carry away all surface drainage, and that if at any time, in the opinion of the Commissioner of Health, the source of supply or the water works system or any part thereof is prejudicial to public health, then such remedial measures shall be immediately adopted as the Commissioner of Health may approve or advise.

SECOND: No additional springs or wells or other sources of supply, and no extension of water pipes, shall be obtained or laid until complete plans showing such sources and the means by which the water is to be collected and until plans of the water pipe extensions proposed shall have been prepared and submitted to the Commissioner of Health for aproval. The Commissioner of Health may modify or amend such plans and fix the conditions under which such additional sources and water works extensions may be obtained and made in order that public health may be safeguarded.

In the case wells should be drilled for an additional source of supply, careful data must be recorded relative to the strata through which the wells have been driven.

Harrisburg, Pa., April 30th, 1908.

CHESTER, DELAWARE COUNTY.

New Chester Water Company.

This application was made by the New Chester Water Company, of the City of Chester, Delaware County, and is for permission to extend its water works system into the borough of Marcus Hook, Delaware county, and to supply water to the public in said borough.

The Commissioner of Health at first determined that the New Chester Water Company appeared to have no right to supply water to the public in the borough of Marcus Hook and the said water company was notified accordingly. Whereupon, its officers formed the Chichester Water Company, which was duly incorporated on December nineteenth, one thousand nine hundred and seven, to supply water to the public in the borough of Marcus Hook, its source of supply to be the Delaware River, the water to be taken therefrom at the present pumping station of the New Chester Water Company in the city of Chester.

The Chichester Water Company has made an application for approval of its system of water works and source of supply, which application is now under consideration by the Commissioner of Health.

It appears that the New Chester Water Company was incorporated under the laws of the State in eighteen hundred and eighty-five for the purchase, erection and maintenance of works for supplying water and furnishing the same for public and domestic use to the city and citizens of Chester, Delaware county, and the suburbs thereof.

At the same time the Penn Water Company, Upland Water Company and South Chester Water Company were incorporated for the same purpose within their respective districts that the New Chester Water Company was incorporated.

The charter territory of the Penn Water Company was confined to the borough of North Chester, that of the Upland Water Company to the borough of Upland and that of the South Chester Water Company to the borough of South Chester, all in Delaware county.

The records in the office of the Secretary of the Commonwealth show that on April sixteenth, eighteen hundred and eighty-seven, the South Chester Water Company had purchased the franchise and all the property of the said Upland Water Company, and of the said Penn Water Company. In turn the South Chester Water Company sold and transferred its franchises and all its property to the New Chester Water Company, the sale being duly recorded in the office of the Secretary of the Commonwealth on November twentieth, Nineteen hundred and six.

On said November twentieth, nineteen hundred and six, the New Chester Water Company had also purchased the franchise and property of the Eddystone Water Company and the Linwood Water Company.

The Linwood Water Company was chartered in December, eighteen hundred and ninety-five, for the purpose of supplying water to the public in the township of Lower Chichester, Delaware county.

The Eddystone Water Company was chartered April nineteenth, eighteen hundred and eighty-seven, for the purpose of furnishing water to the public in all that certain portion of Ridley township in Delaware county, lying south and west of Crum Creek and bordered by said Crum Creek and by Ridley, and the Delaware River. The control of this company was effected by the New Chester Water Company in eighteen hundred and ninety-one, and the latter company immediately laid eight lengths of eight inch pipe on Ninth Street in Eddystone, but no connections with the New Chester Water Company's mains were made or water furnished. Since that time no further work has been done, so the charter lapsed. However, on November nineteenth, nineteen hundred and six, the Eddystone Water Company sold and transferred its franchise and property to the New Chester Water Company. The said defunct Eddystone Water Company should not be confounded with the Eddystone Water Company chartered on December twenty-second, eighteen hundred and ninety-two, for the purpose of supplying water to the public in the borough of Eddystone, Delaware county. The latter company immediately constructed water works and is now furnishing water to the inhabitants of the borough, being operated by the Springfield Water Company.

The act of eighteen hundred and seventy-four and amendments thereto authorize a corporation to sell, assign, dispose and convey to any corporation, created under or accepting the provisions of this act, its franchises and all its property, real, personal and mixed, and thereafter such corporation shall cease to exist and said property and franchises not inconsistent with this act, shall thereafter be vested in the corporation so purchased aforesaid. The doubt as to whether the purchase by one company of the property and franchises of another authorized to furnish water in an adjacent township vested any right in the purchasing company, was generally entertained until the opinion of the Supreme Court in the Hay versus Springfield Water Company case was handed down. This doubt was reasonable because it is a well established fact that a company for the supply of water to the public must confine its operations to a single municipality.

Under this opinion the operations of a water company in several districts by virtue of the purchase of the property and franchises of other companies is not inconsistent with the act which confines the incorporation of such a company to a single district. Said decision was in part as follows:

"Under the act of April seventeenth, eighteen hundred and seventy-six, water companies may sell, assign and convey their franchises and property to other water companies and such properties and franchies will upon such sale and assignment become vested in the purchasing company."

So it appears that today the New Chester Water Company has the right to supply water to the public in the city of Chester, which now includes what was formerly North Chester and South Chester boroughs, in Upland borough and Lower Chichester township, by reason of its having purchased the franchises and property of the above mentioned water companies.

Prior to the rights vested in the Chichester Water Company to supply the inhabitants of Marcus Hook borough the Marcus Hook Water Company was, in eighteen hundred and ninety-two, given a charter covering this territory, but this charter lapsed because the company failed to take any active steps towards furnishing the public with water. The Linwood Water Company territory comprised Lower Chichester township, but at this time (eighteen hundred and ninety-five) Marcus Hook borough had been organized out of Lower Chichester township. It was under the Linwood Water Company's franchise, as previously stated, that the New Chester Water Company thought it had the right to supply the borough of Marcus Hook and so it proceeded to extend its mains in the borough and had laid in the highways therein about three and a half miles of ten, eight and six inch pipes under a borough franchise, whereby a contract exists between the borough and the New Chester Water Company for the maintenance of fire hydrants, it may be presumed that the Chichester Water Company will become possessed of the water pipes and appurtenances and will assume the obligations of the contract under which the New Chester Water Company laid the pipes in Marcus Hook, if it should supply the public there.

The petitioners claim that the Marcus Hook borough franchise is valid and to substantiate this claim call attention to a supplement to an Act entitled, "An Act to enable the south ward of the city of Chester to procure a supply of water, approved the second day of March, eighteen hundred and sixty-seven and the supplement thereto, approved March 24th, 1869," which final supplement was approved March twenty-fifth, eighteen hundred and seventy, and provides as follows:

"Section 1.—That the corporators named in the said act or majority of them, or their successors, or majority of said successors, shall have full power and authority to extend their pipes into any road, street, lane or alley of any township, district and borough in the said county of Delaware, adjacent to the said city of Chester, and shall have full power and authority to supply the inhabitants of the said township, district and borough, or either or any of them with water, and to use all necessary means therefor, as fully as if such township, district or borough had been named in the said original act and its supplements."

"Section 2.—That the proper authorities of any such township, district or borough, or either or any of them, are hereby authorized and empowered to enter into and fulfill all and every such contract and agreement on behalf of such township, district or borough, as may be necessary to fully carry out the purposes of this Act, etc."

It appears that in eighteen hundred and sixty-six a large majority of property owners in the South Ward of the city of Chester voted for a domestic and a fire protection supply of water, and that in the following year a law was passed authorizing the members of the city council of the said South Ward, or a majority of them or their successors, to contract for the erection of works to supply the said South Ward and the inhabitants thereof with an adequate supply of water, and for the purpose power was given to use and occupy the roads of Delaware county, the streets of the city, the streets of said South Ward and other property in the said county, city and ward, with the same rights and privileges, and subject to the same restrictions as are now by law given to and imposed upon water companies in this Commonwealth, et cetera.

The water works, privileges, revenues and franchises were the property of the South Ward and its inhabitants. The security for the payment of the loan contracted for the erection of the water works was all the property in said South Ward, real, personal and mixed.

In eighteen hundred and eighty-seven, the New Chester Water Company bought out the South Ward water works, paying for the system, as it is reported, three hundred and thirteen thousand dollars, and under this purchase and the franchises accompaning it, the petitioners claim the right to extend the pipes of the New Chester Water Company into the borough of Marcus Hook.

This permit is based on the assumption that the said law of eighteen hundred and seventy can be rightfully construed as authorizing the petitioners to supply water in Marcus Hook, although it does not appear that in eighteen hundred and seventy any township or borough in Delaware county was adjacent to the city of Chester except Chester township, Ridley township, and the boroughs of Upland, North Chester and South Chester.

The city of Chester is a manufacturing community and historical town located on the north bank of the Delaware River in Delaware county a short distance above the Delaware-Pennsylvania boundary line and about nine miles down stream from the mouth of the Schuylkill River in Philadelphia. The municipal territory is very irregular in shape and is bounded on the east by Ridley Creek which separates the city from the townships of Nether Providence, Ridley and the borough of Eddystone, the latter being opposite the city along the Delaware River, at the mouth of the creek, on the south by the Delaware River, on the west by Lower Chichester and a part of Upper Chichester township, and on the north by Chester township and Upland borough.

Within this territory which is quite flat and extends along the river bank for a distance of three miles, there is a population of forty thousand people, or thereabouts.

Coming down from the north through the city to the river are numerous streams, the principal one being Chester Creek. It and Ridley Creek and Crum Creek to the east are parallel streams, heading in the hills back in the county and draining farming territory. Their courses are such that numerous mill privileges are afforded. The head waters of Crum Creek furnish a water supply and the head waters of the two other creeks might be available for this purpose, were it not for the excessive damages to mill owners which would have to be paid by any one attempting to divert the water from the streams for public supply. The city is in a thriving condition, its industries, which are varied, among which are the manufacture of textile fabrics, ship building, steel works and tubing mills, et cetera, are located principally along the river front where wharfage is had and also where railroad freight facilities are afforded.

The Delaware River at this point is over a mile wide, the waters are tidal, the normal stage being about six feet and the velocity during the strength of the ebb and flow is very strong. The main channel follows the shores along Chester City.

The main line of the Philadelphia, Baltimore and Washington Division of the Pennsylvania Railroad passes through the city, paralleling the river, and so does the Baltimore and Ohio Railroad.

The highway along the river front is called Front Street and back therefrom parallel streets are designated by numbers. Fulton Street which is at right angles to the river is in the upper or eastern half of the city territory and at the foot of it on the river front the New Chester Water Company's pumping station is located. Chester Creek empties into the river about fifteen hundred feet up stream from the pumping station and Ridley Creek is about one mile still further up stream. While the city has not filed the plans of its existing sewer system, from information now in the Department it is known that there are large public sewers emptying into Ridley Creek in the city of Chester at the foot of Fourteenth, Ninth, and Fourth Streets, which serve an estimated population of three thousand people. Into the main river between Ridley and Chester Creeks there are large public sewers which empty their flow at the foot of Morton, Upland and Welsh Streets. Into Chester Creek there are city sewers discharging at Fourteenth, Seventh, Fourth, Third and Second Streets, serving a combined population of about sixteen thousand people. Below Chester Creek there are large city sewers discharging into the river at the foot of seven streets, if not more. The public sewers are on the combined plan and comprise, all told, a length of about thirty miles, and connected therewith are buildings in which reside thirty-seven thousand people, estimated. The remaining inhabitants occupy properties on which the customary disposal of excrement in privy vaults is in vogue.

There are numerous private sewers from the industrial plants and other places which empty into the streams. Along Ridley Creek in Eddystone borough there are nine boat houses, and Chester Creek there are six boat houses, and along the river in the city there are sixteen boat houses, all of which are much in use during the season. There are overhanging privies at many of these places.

Owing to the method of disposal of sewage both Ridley Creek and Chester Creek are polluted and entirely unsuitable waters to bathe in. Typhoid fever among boys who have bathed therein has been attributed to this custom.

The water company's intake is at such a place that the sewage from the city sewers may be taken by the tide back and forth by said intake, causing in consequence a continual menace of a greater or less degree to public health.

Several years ago the courts were appealed to to compel the water company (prior to its present ownership) to furnish pure water, and this appeal resulted in the installation of the filter plant and the turning on of filtered water for the first time on December third, nineteen hundred and three. No effort has been made by the city to minimize the gross pollution of the river at this point, so that now more sewage than ever of a local origin is discharged into the water supply of Chester City.

The pumping station is a substantial brick structure and therein are housed two Holly-Gaskel crank and fly-wheel compound-condensing pumping engines, each with a rated capacity of five million gallons per twenty-four hours. The machines are old but have recently been thoroughly overhauled and appear to be in good condition. They draw the water through a thirty-inch section main five hundred and fifty feet long, laid on the bed of the river and extending out beyond the Port Warden line a short distance into the main channel. On the end is affixed a strainer. The water here at low tide is twenty-five feet deep.

The water is pumped through about three and a half miles of force main, twenty and twenty-four inches in diameter, a vertical height of two hundred and eight feet, to the reservoir located at Harrison's Hill. The pipe terminates in a gate house at the reservoirs where the water may be delivered into either one of the basins as desired. Each basin is two hundred and twenty feet long by one hundred and fifty feet wide on the bottom, with sloping slides lined with dry rubble masonry to a height of twenty feet or more, and each has a capacity of eight million gallons.

For some years it was the custom to settle the water in one reservoir while supplying the city from the other. To improve the quality of the supply, the company in the year eighteen hundred and ninety-seven, installed a third reservoir of three million gallons capacity, locating same in close proximity to the two reservoirs but at an elevation nine feet lower. With the third reservoir completed, water from the pumps was delivered into reservoir number one and made

to travel the entire length thereof to promote sedimentation, and when it attained a depth of sixteen feet the surface water flowed to reservoir number two through an open spill-way. After additional sedimentation in reservoir number two, the water flowed to reservoir number three, from which it was delivered to the city through the gravity supply mains.

To still further improve the quality of the supply, in the year nineteen hundred and one, the company equipped reservoir number one with wooden baffle boards, to cause a more complete displacement of its contents and to increase its subsidence efficiency. At this time a coagulant feed pump was installed at the pumping station. A solution of sulphate of alumina of uniform density was prepared and applied in known quantities to the water in the force main by means of a small steam pump. In traveling through the three and a half miles of force main between the pumping station and the reservoirs, ample opportunity was given for a thorough admixture of coagulent and water. This method was continued up to the time of installing the filter plant and effected material improvement in the quality of the water delivered to the city, but it did not sufficiently clarify and purify the water.

The filter plant was placed on the hill between reservoirs numbers one and two and the third reservoir. The pumps are operated from twelve to eighteen hours each day to deliver into the two reservoirs the water consumed by the district during twenty-four hours. The maximum daily consumption is reported to be three and a half million gallons and the average one million gallons less.

The filter house is a brick building and it contains twelve mechanical filters, each rated at one-half a million gallons capacity daily. They are operated continuously. The two reservoirs having been pumped full during the day deliver water by gravity to the surface of the filters day and night. In turn, the filtered water goes to the filtered water basin number three. This is an open structure, lined with concrete, two hundred feet long by one hundred and fifty feet wide on top, twenty feet deep, with sides sloped one and a half to one. When full this basin holds three million gallons, but on account of the vertical head room required between the waters in the two reservoirs and that in the third reservoir, the depth of water in the latter is reduced to a maximum of fourteen and a half feet, which is equivalent to a storage of two million gallons only in the filtered water basin.

The arrangement of piping is such that in the case of a large fire, or for any reason, and at will, the water company can turn the water from the sedimentation basins into the filtered water basin, thus by-passing the filter plant. The water in the two sedimentation reservoirs stands at the same level and may be lowered about four feet, equal to about one and a half million gallons, before the filters cease to be operated by gravity. The remaining water is available by pumping. A centrifugal pump, capacity not stated, has been set up in the gate house located between the two sedimentation basins, which when necessary lifts water from basin number one into basin number two.

The wooden baffle boards in basin number one, were in the Fall of nineteen hundred and seven partly broken down, so that the water instead of traveling around them passed through.

The coagulant solution which is mixed or prepared in two tanks in the filter house, and is dissolved sulphate of alumina, is added to the water as it enters the sedimentation basin at the gate house. The amount of solution used is regulated by floats and the strength is said to be about one-quarter grain per gallon. Tests are not made at regular intervals to ascertain whether this amount be sufficient to purify the water at all times.

The drainage facilities for the wastes from the plant are not stated by the applicants. In fact, the company has failed to file plans of the reservoirs and purification plant sufficiently in detail to enable the Department to judge accurately as to the suitability of the apparatus as a safeguard to public health.

Each of the twelve filter units is a cypress tank, fifteen feet inside diameter. They are arranged in parallel rows of six units each with the operating gallery and piping and accessories on and underneath this gallery. The influent pipe of each filter is provided with a balance valve and float for maintaining the desired water level within the filter and to prevent its overflowing. The effluent valve is also provided with a valve and float to shut off the filters when the level of water in the filtered water collecting flume reaches an established maximum elevation. No rate controllers are provided, however, so there is nothing to prevent the operation of a filter unit at a speed far beyond its capacity to purify the water.

It is understood that across the centre of each filter on the bottom is laid a cast-iron main collector, and extending laterally from this to within three inches of the inside periphery of the tank, on six inch centres, are one and one-quarter inch diameter extra heavy wrought-iron pipes which receive the screens or strainers. The bottom is filled with concrete three and one half inches deep to the top of the screen, on top of which is placed six inches of gravel varying in size from one-eighth to one-half inch diameter, and on top of the gravel is placed about three feet of sand, having an effective size of about four-tenths milimeters and average uniformity coefficient of one and a half.

The floor of the filter house is concrete throughout. The operating platform is built of wood and is located about three feet below the top of the filters, and on this are mounted the stands of the operating gates. Below it in the concrete foundation is constructed the filtered water flume, which is six feet wide by four feet

deep and one hundred feet long. The water in it is the same height usually as the water in the filtered water basin, there being a twenty inch pipe connection between the two. The basin adjoins the filter house. The flume not being covered receives the dirt which falls through the cracks of the platform over it. At the time of the Department's inspection, there was considerable sediment on the bottom of the flume.

The filters are cleansed with a reverse or upward current of filtered water, supplied by centrifugal pump, rated at twelve hundred gallons per minute, which takes its suction from the filtered water collecting flume. A mechanical agitator or rake for stirring up the sand layer to its extreme depth, or on the surface only, is provided. This method of surface agitation for the removal of intercepted matters from the surface of the sand layer is stated to have been installed for the first time at the Chester plant. Instead of being provided with one waste located twelve inches above the sand layer, the filters have two waste openings, one immediately at the level of the sand layer, and the other twelve inches higher, both connected with a steel trough. The filter undergoing cleaning is first drained off until not over twelve inches of water remain over the sand layer. The surface accumulations are then broken up by the agitator and form with the remaining water a thick mass which is drained off completely to the level of the sand bed through the lower opening. The bulk of the intercepted matters thus removed, washing with a reverse current, proceeds, the water overflowing through the upper opening, the agitator being used or not as necessity may require. The advantage claimed for this particular method is that by it the surface accumulations only may be removed and filtration resumed without disturbing the lower strata of the sand level or interfering with its filtering functions. Whether or not the plan is operated in a manner to make this process advantageous is not proven by the data now in possession of the Department. The storing up of impurities in the lower layers of the filter might be a disadvantage.

It is reported that after the unit is put in operation again the filtered water for the first fifteen or twenty minutes is turned into the waste water flume, and that after this the filter is ran at one-third of its rate for several hours. Six filters are cleansed this way each day. An attendant is constantly on duty. The waste water from the filters is collected in an open flume in a concrete floor of the house (one flume in front of each row of filters), which delivers the waste to a well adjoining the filter house. The water after subsidence is pumped from this well into sedimentation basin number one. What disposition is made of the sediment is not stated. The waste flume is not covered and it is possible for the dirty water to splash over or by accident to reach the filtered water in the larger flume paralleling the two smaller ones and immediately adjacent thereto.

Bacteriological tests of the efficiency of the purification plant have shown ninety-nine per cent removal of bacteria from the raw water as reported by the petitioners.

It is reported that there are about thirty-six hundred consumers in the water district, of which in the city of Chester, out of a total population of forty thousand, there are thirty-four thousand one hundred and ten consumers; in the borough of Upland, out of a total population of twenty-three hundred, there are seventeen hundred and fifty consumers, and in Lower Chichester township, out of a population of fifteen hundred, there are one hundred and forty consumers. The system of distributing pipes comprises about fifty-eight miles, ranging in diameters from twenty-four inches to two inches. Owing to the growth of population and developments the petitioners wish to extend the mains.

There are about twelve hundred private wells in the city, fifty in Upland borough, and two hundred or more in Lower Chichester township, so it is reported.

The records of the local health officials do not show that diminution in typhoid fever rates which might be expected to follow the installation of a water purification plant. In nineteen hundred and six, there were sixty-two cases and twenty-four deaths reported to the State Department. In all probability the records are not accurate. More cases may have occurred than were recorded. The ratio of deaths to cases seems to warrant this conclusion. At least ten of the deaths in nineteen hundred and six occurred at the City Hospital. Up to October, nineteen hundred and seven, there were fourteen cases of typhoid fever for the year in Lower Chichester township, in ten instances of which the sufferers used well water. Whether the prevalence of this disease in the water district is due to polluted milk, well or public water of local origin is entirely debatable. A special study would have to be made to settle the question. One conclusion, however, is warranted, which is that well water drawn from the ground in proximity to privy vaults or cesspools or from ground that may have been saturated with sewage in the past, or from ground from the surface of which pollution may reach the wells, is dangerous and should be stopped.

Besides building new mains in the present district the petitioners ask approval of the extensions into Marcus Hook, as aforesaid.

This borough is a small manufacturing community located on the north bank of the Delaware River immediately below the city of Chester. There is a small strip of land in Lower Chichester township between said city and the borough. Said township also bounds the borough on the north. The State line between Delaware and Pennsylvania bounds the borough on the west. Within this incorporated territory, which comprises about four hundred acres and lies low and flat, there are at

present about fifteen hundred residents mostly employed in the oil refineries, but some of them are engaged in shad fishery. The Pennsylvania Railroad lines pass along the northern boundary and a branch of the Reading Railroad terminating in the town, extends along the river bank up stream to Philadelphia. The town has attained some note as the location of the State Quarantine Station. It is also the terminasi of the petroleum oil pipe lines from the productive fields of western Pennsylvania to the seaboard. It is from here that oil is exported to foreign countries.

At present the citizens obtain drinking water from individual wells mostly dug through hard-pan into underlying gravel. Kitchen slops and garbage are deposited on the ground and surface and shallow privies abound. Opportunities are many for surface and sub-soil pollution of the drinking supply. Cases of typhoid fever occurring in the borough have been attributed to polluted well water. The town is in need of sewerage and the question is now being considered. The local authorities hope by an aggregate policy of public improvement involving water and sewerage works, to promote the industrial growth and material prosperity of the community. Provided the petitioners have a charter right to furnish water in this district, there apepars to be no reason why permission therefor should not be granted.

The State Department of Health is endeavoring to stop the discharge of sewage into the creeks which pass through Chester City, and some progress has been made in the territory outside of the city. While the sewage of Philadelphia and of other cities in the Delaware River basin goes into the streams there, there are opportunities for dilution and destruction by natural processes of much of the poisonous matter, so that when the waters originally freighted with such sewage pass by the intake of the New Chester Water Company's system, it is not likely to be so dangerous as the virulent sewage poisons which are discharged into the river in the immediate vicinity of said intake and passing thereby. The latter sewage being the most dangerous should be the first sewage to be diverted from the city's water supply. Even then the Delaware River water will be dangerous. These facts should constantly be borne in mind by those upon whom rests the responsibility for supplying the people of Chester and vicinity with pure and wholesome water. Too great care cannot be exercised in operating and maintaining the purification plant. Its normal capacity would seem to be sufficient for the additional demands which may be made upon it soon, but it is evident that to maintain a high state of efficiency other units must be added at no distant date, provided the water district be materially increased.

In view of the foregoing considerations, it has been determined that the proposed source of supply to Marcus Hook borough will not be prejudicial to the public health, and a permit is hereby and herein granted therefor and for the extension of the water works in the streets as proposed, under the express stipulations that the right to do the things proposed is within the rights of the New Chester Water Company's charter and the laws of the State, and under the further conditions and stipulations as follows:

FIRST. The water company shall within six months from the date of this permit file in the office of the State Department of Health complete and full detail plans of the reservoirs, filter plant, grounds, piping, gates and appurtenances thereof, together with a plan of all water pipe owned by it and laid in the borough of Marcus Hook and Lower Chichester township. And thereafter, at the close of each season's work, the company shall file a plan of the pipes laid during the year in said office, together with such other information in connection therewith as may be required.

SECOND. Weekly reports of the operation of the water works system, particularly the purification plant, shall be kept on blank forms satisfactory to the State Department of Health, and copies thereof shall be filed in said Department. The water company shall assist the State Department of Health in making such tests of the plant from time to time as may be found desirable. If necessary, the Commissioner of Health may prescribe standards of efficiency and make regulations for the operation and maintenance of the plant. If at any time in his opinion the water works, or any part thereof, or the water furnished thereby, has become defective, or insufficient or prejudicial to the public health, then such remedial measures shall be adopted by the said company as the Commissioner of Health may advise or approve.

THIRD. The introduction of raw river water into the street main system or anywhere except into the subsidence basin is absolutely prohibited. Duplicate pumps or ample pumping capacity shall be provided at the gate house or subsidence basins to render as much of the eight million gallons stored in reservoir number one as may be practicable available for use. With the large storage now available on the hill, ample insurance against the necessity of by-passing the filter plant should be afforded. There being facilities for storing two million gallons of filtered water, the necessity does not exist for an emergency connection between the pumps and the street mains. To the contrary, the interests of the public health demand that all connections with the force main between the pumps and the purification plant shall be absolutely cut off or discontinued if there be any such. So this is made a special stipulation.

FOURTH. The filtered water flume and the wash water flumes shall be covered by a water-tight concrete floor to obviate any possible contamination of the filtered water.

FIFTH. Rate controllers of approved design shall be installed on the filters and no unit shall be operated beyond its normal capacity, except it be in an emergency.

SIXTH. The water company shall have bacteriological tests made of the raw water and of the water in its various stages of progress through the purification plant, and this shall be done in a most thorough manner every six months. Every two weeks bacteriological tests of the filtered water shall be made in sufficient numbers to show whether the plant is efficiently performing its work. Copies of these tests shall be promptly submitted and filed in the office of the State Department of Health.

The Commissioner of Health will request local authorities to have a systematic test made of well water in the water district and will do other things also in an attempt to bring about a dimunition of typhoid fever there. He will also, in conjunction with the Governor and Attorney General, take some action with respect to the sewage pollution of the Delaware River and tributaries by Chester City sewage as may be determined to be proper and necessary. The city Board of Health will be requested to stop all bathing in the sewage polluted streams of the vicinity, also said Board will be advised that all wells in the city used as sources of drinking water should be tested and, if found polluted, the same should be abandoned.

Harrisburg, Pa., March 23, 1908.

CHESTER TOWNSHIP, DELAWARE COUNTY.

Edgemont Water Company.

This application was made by the Edgemont Water Company of Chester Township, Delaware county, and is for permission to establish a system of water works and supply water to the public within said township.

The Edgemont Water Company's charter was approved on March fourth, one thousand nine hundred and eight, and authorized said company to supply water to the public in the township of Chester, Delaware county, its source of supply to be the Delaware River, the point on said river at which said water is to be taken or used, to be at the present pumping station of the New Chester Water Company in the city of Chester.

The incorporators are men who are interested in the New Chester Water Company and the latter will sell water to the Edgemont Water Company.

The township of Chester, which it is proposed to supply, lies directly north of the city of Chester, being bounded on the east by Ridley Creek and on the west by Chester Creek. The only settlement of any magnitude in the township is the village of Brookhaven. It is in the north central part of the township and has a population of possibly seventy-five people. The entire population of Chester township in nineteen hundred was five hundred and forty-three. The filter plant and distributing reservoir belonging to the New Chester Water Company are located at the extreme northern limits of this township and the twenty-four inch supply main returning to the city from the distributing reservoir on the hill, is laid in the turnpike which passes through Brookhaven village. Along the one and a half miles of turnpike in the township are located a number of houses, several of which are connected with the said supply main. These dwellings have been so supplied with water for a number of years.

The present owners of the New Chester Water Company recently discovered that these properties supplied with water in Chester township were being furnished with water without legal authorization, and, therefore, the Edgemont Water Company was incorporated to legalize this supply and the furnishing of water to anybody who might want it within said township.

No plans have been submitted by the petitioners except a sketch of the supply main above mentioned and it is not known that the new company purposes to immediately lay any pipes in the ground.

The New Chester Water Company pumps water from the Delaware River, taking it at a point opposite the central part of the city in the main channel where the sewage from the city sewers and that from Philadelphia nine miles distant has opportunity to pass and repass the intake. The water is pumped through a rising main whose diameter ranges from twenty to twenty-four inches a distance of about three and a half miles to two sedimentation basins, each holding eight million gallons. Adjacent thereto, there is a mechanical filter plant, the water flowing from these basins after treatment with a chemical solution, onto the filters. They have a normal capacity of six million gallons daily. The filtered water flows to a filtered water basin holding two million gallons. This plant is on Harrison's Hill in the northern part of Chester township. The distributing system extends through the city of Chester, Upland borough and in a part of Lower Chichester township. The daily consumtion averages less than three million gallons. The population supplied approximates thirty-six thousand. The purchase of the franchise and property of the Linwood Water Company and of the Upland Water Company in a manner prescribed by law is the authority under which the New Chester Water Company has the right and is exercising it to furnish water to Lower Chichester township and Upland borough; also possibly under a supplement, approved May twenty-fifth, eighteen hundred and seventy, to an act of eighteen hundred and sixty-seven,

enabling the South Ward of the city of Chester to produce a supply of water, and the supplement thereto of eighteen hundred and sixty-nine. Under this law it is claimed by the New Chester Water Company that it has full power and authority to extend water pipes into any road, street, etcetera, of any township, district and borough adjacent to the city of Chester in the county of Delaware. If this construction of the law be correct, then the New Chester Water Company already has authority to supply the public with water in Chester township.

It is, of course, understood and presumed that the Edgemont Water Company will not purchase water of the New Chester Water Company at any point where the New Chester Water Company is not under its charter and franchise empowered to sell water to the public.

The petitioners should not sell water to the public unless it be pure and wholesome, but the Edgemont Water Company now has no control or means known to the Department of regulating this matter. The petitioners do not purpose to build a filter plant of their own. They intend to sell the water of the same quality as it is purchased. In this arrangement the Edgemont Water Company does not seem to have afforded sufficient safeguard to their consumers. The Commissioner of Health must, under the law, determine whether the proposed supply be prejudicial to the public health. There is no doubt if the Edgemont Water Company should enter into an agreement compelling the New Chester Water Company to furnish a pure and wholesome supply at all times to it under forfeiture of a sufficient amount, that this could be taken as one reasonable evidence of the intention of the Edgemont Water Company to actively interest itself in the potability of the water which it is authorized to supply to the public.

The fact cannot be emphasized too much that the original source, the Delaware River, is dangerous. There are always poisons therein inimical to life and health. An accident might occur, but under such circumstances carelessness and negligence more often do occur, whereby a greater or less amount of these poisons are admitted through the water pipe into the homes of the consumers. Constant vigilance should be exercised in the operation of the purification plant, else the water to be purchased by the Edgemont Water Company would be unsuitable to supply to the public.

It has been determined that the proposed water works system and the supply therefor for the township of Chester by the Edgemont Water Company will not be prejudicial to public health, and a permit is hereby and herein granted therefor, under the following conditions and stipulations:

FIRST. This permit shall not be operative until the Edgemont Water Company shall have entered into an agreement with the New Chester Water Company, whereby the latter shall guarantee to furnish the former with a sufficient quantity of water, the purity of which shall be satisfactory to the State Commissioner of Health. Tests of this water shall be made by the Edgemont Water Company every two weeks and copies thereof shall be filed in the office of the State Department of Health. A copy of said agreement shall also be filed in said office.

SECOND. Before the Edgemont Water Company shall lay any water pipes and use the same, plans thereof shall be filed in the office of the State Department of Health and be approved. At the close of each season's work a plan of the water mains laid during the year shall be prepared and sent to the Commissioner of Health, to the end that there shall be a complete record in said office of the extent of the works belonging to the Edgemont Water Company and the number of people in said township dependent upon such supply.

THIRD. If at any time, in the opinion of the Commissioner of Health, the water supply, or the water works, or any part thereof, has become prejudicial to public health, then the Edgemont Water Company shall adopt such remedial measures to protect the public health as the Commissioner of Health may approve or suggest.

FOURTH. Regular inspections will be made of the Edgemont Water Company's system and supply by a Department officer. The Commissioner of Health may suggest rules and regulations to govern the supply of water to the public in so far as public health is concerned. Said water company shall conform to any such orders, rules or regulations in so far as they may relate to the supply of water to the public in Chester township.

FIFTH. This permit is issued on the express stipulation that the operations of the Edgemont Water Company shall be wholly within its charter rights.

Harrisburg, Pa., March 23, 1908.

CHESTER, DELAWARE COUNTY.

New Chester Water Company.

This application was made by the New Chester Water Company of Chester, Delaware county, and is for a modification of a permit issued to the said company by the Commissioner of Health under date of March twenty-third, one thousand nine hundred and eight.

It appears that in said permit, Section Five, it was stipulated as follows:

> "Rate controllers of approved design shall be installed on the filters and no unit shall be operated beyond its normal capacity except it be in an emergency."

The applicants beg to be excused from this provision because the outlay involved is large and because in the bottom of each filter there is a six inch manifold in which all of the clear water passing through the filter bed is collected before passing to the clear water flume outside. Since the diameter of this manifold is six inches and the diameter of the pipe and connection into the clear water flume is five inches, and since a six inch pipe under a ten foot head will deliver about five hundred thousand gallons daily, whereas a five inch pipe can only deliver four hundred and twenty-five thousand gallons daily when there is a full height of water on the filter, this provision, especially installed to obviate the cost of putting in rate controllers, successfully regulates the flow of effluent from the filter and serves the purpose as thoroughly as would some other kind of rate controller. It is urged by the applicants that of the many different patterns of controllers none is an absolute success and none is to be preferred to the simple arrangement above described. Therefore, since it would cost several thousand dollars to install other rate controllers on the twelve filter units at the plant, the New Chester Water Company deems these facts a sufficient warranty for the Commissioner of Health to relieve the petitioners from the provision of Section Five of said permit.

It has been determined that the request can be complied with without prejudice to the public health and, therefore, the said permit of March twenty-third, one thousand nine hundred and eight, is hereby and herein modified by striking out the fifth clause or stipulation thereof.

Harrisburg, Pa., April 20, 1908.

DANVILLE, MONTOUR COUNTY.

Danville State Hospital for the Insane.

This application was made by the Board of Trustees of the Danville State Hospital for the Insane of Danville, Montour county, and is for approval of plans for additions to the present water purification plant submitted in pursuance of recent legislation and an appropriation made therefor, said permit and approval being given under the following conditions and stipulations:

It appears that the present plant consists of a gravity intake, pump well, feed water pump, sedimentation basin, two filter units, filtered water basin and high service pumping machinery. The works were established in one thousand nine hundred and three, having been laid out and constructed under plans furnished by the New York Continental Jewell Filtration Company. The tank and filters, the pump well and filtered water basin comprises one structure, about fifty-five feet long by nineteen feet wide. It is located adjacent to the high service pumping station for the hospital. The water from the river first enters the pump well outside on the flats and then by pipe to the raw water pump located in a pit extending clear across the end of the building below ground and having a width of ten feet and a depth of nine and one half feet below the floor line. This floor line is about level with the surface of the ground outside. From here the water is lifted into the sedimentation tank which is a wooden structure, fourteen feet in diameter and ten feet high, provided with customary baffles, inlets and outlets, such as are used in plants of this type. The drainage from this tank is discharged into the sewers of the plant whose outlet is ultimately into the river below the intake.

From the subsidence basin the water flows by gravity to two filter units, each twelve feet in diameter, of the low type standard double tank, reversible rake bar Jewell filter, each having a rated capacity of three hundred thousand gallons per twenty-four hours and designed to be operated in excess of this rate for short periods. Each filter is of double tank construction. The inner tank, or filter receptacle is twelve feet inside diameter and the over-all height of the double tank is eight feet. The water is introduced between the inner and outer tanks and rising up passes over the edge and into the filter. The level of the surface of the sand is twelve inches below top of the filter tank and the depth of sand and gravel is three feet eight inches. This material rests on the strainer system, which consists of a central eliptical cast-iron header constructed in flanged sections securely bolted together. The header is tapped on opposite ends of its long diameter for the lateral pipes. The laterals are spaced six inches on centers and are one and one-fourth inch wrought-iron pipes, inner end screwed into the cast-iron headers and the free end capped. These laterals are drilled and tapped on the top six inches apart with three-eight inch pipe, upon which the brass strainers are fitted. These strainers are provided, four per square foot of filtering area. The screen system is imbedded in concrete up to a level with the upper portion of the strainers. From the collecting system the filtered water is delivered into a down draft pipe five inches in diameter extending down six feet into the clear water well, the end being about two feet above the bottom of said well.

In each filter there is provided a rotary reversible swivel rake bar agitator, mounted on heavy yellow pine cross timbers and supported in suitable cast-iron brackets attached to the sides of the filter tank. The agitator consists of a system of spur and bevel gear and pinion with tight and loose pulleys, shaft and belt shifting device, so that the agitator may be revolved with the rakes traveling in a vertical position or reversed and the rakes made to trail over the surface of the filter beds.

The function of the down draft pipe is to act as a controller when the clear water well is full. Excessive use, however, from the clear water well tending to uncover the down draft pipe exerts a suction or down draft on it, thereby increasing the flow from the filters, and might tend to exceed their proper capacity.

The influent pipe to each filter is six inches in diameter controlled by a flanged gate valve.

The filter is washed by reversing the current and the waste water is drained into the eight inch sewer above mentioned. There is a re-wash arrangement whereby the first filtered water may be wasted to the sewers, all provided with and controlled by proper valve arrangements. The waste pipe from each tank is four inches in diameter. The pressure from the service system of the institution is used for washing.

On each influent pipe to the filter there is a butterfly valve controlled by means of a float encased in cast-iron float tank attached to the side of the filter unit, whereby the supply of water to the filter is regulated.

The chemical feed box is located in the room over the pump pit and there are two storage tanks. The feed is through a regulation orifice box into the section pipe of the raw water feed pump. This pump has a capacity of six hundred thousand gallons, so it is reported. It is of the direct acting type.

The pit or well in which this pump is located is constructed water tight. The water flows to the pump by gravity.

The consumption of water at the institution is equal to about the rated capacity of the filter plant. On the hill back of the main building there is a storage reservoir. In the operation of the water works during the hours of greatest consumption the pumps are speeded up in the adjacent station to a rate in excess of the normal capacity of the filters with the result that the water is lowered in the clear water basin beneath the filters to the minimum and, as above explained, the rates of the filters are accelerated and at times, especially during high turbidities in the river, the evidence of over crowding of the filters may be seen in the coloring in filtrate. To obviate the possibility of overcrowding of the plant, the Trustees propose to add one filter unit and additional filtered water storage.

The filtered water basin is underneath the subsidence tank and the present filter units and its dimensions are nineteen feet in width by forty-five feet six inches in length and a depth of ten feet. Probably eight feet of this depth is effective capacity. Into this basin the suction pipes of the service pumps are extended. These pumping engines are ample in capacity to serve the institution. The raw water feed pump, however, is of insufficient capacity. The present installation should be taken out and duplicate machinery provided, centrifugal pumps installed each having a capacity ample to deliver all the water that may be required during any interval of time to the plant.

The plans submitted for a new filter unit provide for construction similar in all respects to the filter units now in existence. The end wall of the superstructure enclosing the filters is to be torn out and the filtered water basin and superstructure is to be extended about fourteen feet. Thus the storage capacity for filtered water will be increased and the full capacity will be equivalent to nine hundred thousand gallons of filtered water per twenty-four hours. The filtered water basin is to be constructed of concrete and the superstructure is to be built of brick.

The filter company proposes to give a guarantee of efficiency to extend over one year from the completion of the new filter unit. The guarantees are made subject to the conditions that the plant shall be operated in accordance with the instructions of the filter company and that a suitable quantity and quality of coagulants or reagents shall be used. When operated in this manner the new filter unit is to deliver three hundred thousand gallons of clear bright water, practically free from color and matters in suspension.

It has been determined that the proposed filter unit and additional storage capacity for filtered water will not be prejudicial to public health, and the plans are hereby approved therefor under the following conditions and stipulations:

FIRST: The improvements shall be made in conformity with these plans and thereafter the plant shall be operated in an efficient manner, satisfactory to the Commissioner of Health. Daily reports of the operation of the water works system shall be kept on blank forms satisfactory to the State Department of Health and copies thereof shall be filed in the office of the Commissioner of Health.

SECOND: It is the purpose of the State Department of Health to collect samples of the raw water and the filtered water and to watch the operation of the system, and if at any time, in the opinion of the Commissioner of Health, the plant or any part of the water works system is prejudicial to public health, then such remedial measures shall be adopted as the Commissioner of Health may suggest or approve.

THIRD: The Board of Trustees shall provide adequate and duplicate pumping machinery for the raising of raw river water into the filter plant and attention is called to the suggestions hereinbefore made relative to this point.

FOURTH: The Trustees shall prepare an accurate detail plan of the existing pumping station and layout, including the intake pipe, the run nearby, the railroads, adjacent buildings, location of valves and force main and file the same in the office of the Commissioner of Health on or before the completion of the filter unit herein approved.

It would appear from evidence at hand that an examination of the intake pipe at the river and leading therefrom to the receiving well on the flats should be carefully made by some qualified expert in the employ of the Trustees. Probably

defects in this line may be found and remedies applied, whereby an ample quantity of water may be assured at all times at the pump well and raw water feed pumps.

Harrisburg, Pa., August 14th, 1908.

DANVILLE, MONTOUR COUNTY.

This permit is issued to the Board of Trustees of the State Hospital for the Insane at Danville, Montour county, and is for the construction of additional filter units to the present water filtration plant of the institution, according to plans therefor filed by Mr. William Field Shay, President of said Board of Trustees.

It appears that the present plant consists of a gravity intake, pump well, feed water pump, sedimentation basin, two filter units, filtered water basin and high service pumping machinery. The works were established in nineteen hundred and three, having been laid out and constructed by the New York Continental Jewell Filtration Company. On August eleventh, nineteen hundred and eight, said filtration company submitted plans for improvements to the works; the plans were approved and a permit issued therefor by the Commissioner of Health, said permit being dated August fourteenth, nineteen hundred and eight. This permit was issued with the understanding that the plans had been authorized by the Board of Trustees. It now appears that this was a mistake. After advertisement and the receiving of bids, the trustees, represented by the President, Mr. Shay, are prepared to enter into a contract with the American Water Softener Company, provided the plans submitted by this company are satisfactory and receive the approval of the Commissioner of Health as required by law.

The present tank and filters, pump pit and filtered water basin are all housed in one structure, fifty-five feet long and nineteen feet wide. This building is located adjacent to the high service pumping station for the hospital.

There is a receiving well on the flats between the station and the river into which the raw river water flows by gravity and from which it flows by gravity to the feed water pump located in the pit under one end of the building. However, this gravity flow to the pumps is only during a period of high water in the river. There are weeks at a time when there is a suction lift of twenty feet or thereabouts. The pump pit is ten feet wide with a depth of about nine and a half feet below the floor. In it there is a horizontal simple duplex pumping engine of a rated capacity of about eight hundred thousand gallons per twenty-four hours. This engine lifts the water into the sedimentation tank located on the floor of the building above. This structure is fourteen feet in diameter and ten feet high and provided with customary baffles, inlets and outlets, such as are used in plants of this type. The drainage from this tank is discharged into the sewer outlet of the plant, whose outlet is ultimately into the river below the intake.

From the subsidence basin the water flows by gravity to two filter units, each twelve feet in diameter, of the low type, standard double tank, reversible rake bar, Jewell filter, each having a rated capacity of three hundred thousand gallons per twenty-four hours and designed to be operated in excess of this rate for short periods. Each filter is of double tank construction. The inner tank, or filter receptacle, is twelve feet inside diameter and the over-all height of the double tank is eight feet. The water is introduced between the inner and outer tanks and rising up passes over the edge and into the filter. The level of the surface of the sand is twelve inches below the top of the filter tank and the depth of sand and gravel is four feet eight inches. This material rests on the strainer system, which consists of a central eliptical cast-iron header constructed in flanged sections securely bolted together. The header is tapped on opposite ends of its long diameter for the lateral pipes. The laterals are spaced six inches on centres and are one and one-quarter inch wrought-iron pipes, inner end screwed into the cast-iron header and the free end capped. These laterals are drilled and capped on the top six inches apart with three-eighths inch pipe, upon which the brass strainers are fitted. These strainers are provided four per square foot of filtering area. The screen system is imbedded in concrete up to a level with the upper portion of the strainers. From the collecting system the filtered water is delivered into a down draft pipe five inches in diameter extending down six feet into the clear water well, the end being about two feet above the bottom of said well.

In each filter there is provided a rotary, reversible, swivel rake bar agitator, mounted on heavy yellow pine cross timbers and supported in suitable cast-iron brackets attached to the sides of the filter tank. The agitator consists of a system of spur and bevel gear and pinion with tight and loose pulleys, shaft and belt shifting device, so that the agitator may be revolved with the rakes traveling in a vertical position or reversed and the rakes made to trail over the surface of the filter bed.

The function of the down draft pipe is to act as a controller when the clear water well is full. Excessive use, however, from the clear water well tending to uncover the down draft pipe exerts a suction or down draft on it, thereby increasing the flow from the filters, and might tend to exceed their proper capacity.

The influent pipe to each filter is six inches in diameter controlled by a flanged valve gate.

The filter is washed by reversing the current and the waste water is drained into the eight inch sewer above mentioned. There is a re-wash arrangement whereby the first filtered water may be wasted to the sewer, all provided with and controlled by proper valve arrangements. The waste pipe from each tank is four inches in diameter. The pressure from the service system of the institution is used for washing.

On each influent pipe to the filter there is a butterfly valve controlled by means of a float encased in a cast-iron float tank attached to the side of the filter unit, whereby the supply of water to the filter is regulated.

The chemical feed box is located in the room over the pump pit and there are two storage tanks. The feed is through a regulation orifice box into the suction pipe of the raw water feed pump.

The consumption of water at the institution is equal to about the rated capacity of the filter plant. On the hill back of the main buildings there is a storage reservoir. In the operation of the water works during the hours of greatest consumption the pumps are speeded up in the adjacent station to a rate in excess of the normal capacity of the filters, with the result that the water is lowered in the clear water basin beneath the filters to the minimum and, as above explained, the rates of the filters are accelerated and at times, especially during high turbidities in the river, the evidence of overcrowding of the filters may be seen in the coloring in the filtrate. To obviate the possiblity of over-crowding of the plant, the Trustees purpose to add one filter unit and additional filtered water storage.

The filtered water basin is beneath the subsidence tank and the present filter units, and its dimensions are nineteen feet wide by forty-five feet six inches long and ten feet deep. Probably eight feet of this depth is effective capacity. Into this basin the suction pipes of the service pumps are extended. The high service pumping engine which is used to serve the institution has a capacity of nine hundred gallons per minute. There is an emergency high service engine of about the same capacity.

The raw water feed pump is of sufficient capacity to deliver all the water that may be required during intervals of excessive demand at the plant.

There are five proposals made by the bidders whose plans are under consideration.

Proposal "A" comprises the extensions of the existing filter building and clear water basin a distance of fifteen feet and the installation of one additional twelve foot diameter double tank gravity filter, identical in all respects with the existing filters, excepting that the filter offered herein is to be equipped with the Hodkinson improved, reversible, power agitator, which is claimed to possess the additional advantage of throwing the wash water into the wash or waste gutter and expediting the washing process, and the filter is also to be equipped with the Hodkinson improved strainer or sand valve.

Under this proposal the filter house shall be extended in a neat and substantial manner, all walls to be of same thickness as walls of the existing buildings; all materials to be of the same quality, the filtered water basin to be of the same depth, breadth and construction; the "I" beams for supporting the filter to be of same weight and depth; the roofing and covering to be the same; the operating platform to be the same; all window frames, sash and lights to be the same, and the whole completed in a thorough and workmanlike manner and the equal in every particular of the existing building as regards finish, workmanship and quality of materials. This proposal contemplates removing the existing end wall of the filter house, but with the understanding that the brick, window frames and sash may be used in the proposed extension.

The proposal also contemplates extending the operating platform. It also includes all hangers, shafting, pulleys and belting for driving the agitator on the new filter.

As the present eight inch diameter pipe leading from the subsidence tank is too small to supply an additional filter, the proposal contemplates removing the present eight inch supply and substituting therefor a ten inch diameter wrought-iron supply main, properly valved, with a branch therefrom to each of the existing filters, and to the filter offered in the proposal, the free end of this pipe to be capped or plugged to admit of extending it to future filters.

Under this proposal it is agreed to extend the existing wash water supply, steam sterilizing and drain pipes to the new filter, carrying the effluent from the filter down into the filtered water basin, and the doing of all other pipe work incident to the proper installation of the filter herein proposed and necessary to make it complete and identical in all respects with piping arrangements on the existing filters.

This proposal also contemplates the furnishing and installation of all materials, although not herein specifically referred to, necessary to extend the filter building and the existing filtered water basin, to install the additional filter and make everything complete and first class and in running order, everything to be equal in every respect to the existing plant and to harmonize therewith.

Proposal "B" provides for the extension of the existing filter building and filtered water basin a distance of twenty-nine feet six inches and the installation of two twelve foot diameter filters, all as set forth in Proposal "A."

Proposal "C" is on the assumption that the filtered water basin is to be omitted and concrete footing courses furnished for new walls, and on this basis a deduction is to be made from Proposal "A" and also from Proposal "B" of two hundred and fifty-three dollars and five hundred and six dollars respectively. Under this proposal the new portion of the building would be covered with a substantial and well finished concrete floor laid off in squares and the filter effluents would be carried down into the existing filtered water basin.

Proposal "D" is the same as proposal "A" practically, with the exception that instead of a twelve foot filter, it is proposed to establish a standard thirteen foot filter, the same to be constructed in all substantial respects as the standard fifteen foot filter of the bidders. Each of the existing filters at the institution is twelve feet in diameter and there is an area of one hundred and thirteen square feet. The thirteen foot filter proposed has an area of one hundred and thirty-two square feet, or nearly seventeen per cent. more area and capacity than each of the existing filters. The bidders offer to give this additional filter capacity without extra cost. The unit would not look unlike the existing filters and the present existing appearance of the plant would be maintained. But under this proposal the company would install its own style apparatus instead of a double tank filter like those now in use at the plant.

Proposal "E" is substantially the same as Proposal "B", with the exception that each of the two additional filters is to be of the bidder's own make and each thirteen feet in diameter. The two filters offered in this proposal would give nearly thirty-four per cent. greater filter capacity than two filters like those already in use.

The bidders guarantee the filters herein offered by them to be capable of delivery under like conditions, a quantity and quality of water equal in every respect to that produced per square foot of area by the existing filters at the institution; and that the filters proposed will consume no more time or wash water in cleaning and that no more power will be required to drive the agitator.

The filters proposed and all parts thereof are guaranteed free from infringement of patents.

Proposal "A" is for the sum of Three thousand two hundred and ninety-two dollars. Proposal "B" is for the sum of five thousand nine hundred and eighty-nine dollars.

The bidders are prepared to extend the filter house and install two additional filter units within one hundred days or one additional filter unit within seventy days.

The method now in use at the plant for applying the coagulant solution is not accurate, or it does not receive the personal attention necessary to make it accurate. As above stated, this is a gravity feed device and feeds a constant stream at all times regardless of the quantity of water flowing to and through the filters. This would be all right if the strength of the solution added varied in conformity with the quality and quantity of water delivered. As it is now, if the device is adjusted to feed a given amount when the filters are clean, it will supply too much coagulant as the filters become dirty, because more water is furnished to the filters when they are clean than when they are dirty, and the rate of filtration is much reduced. If the device is adjusted when the filters are dirty, it will, therefore, feed too little coagulant when they are clean for the same reason. Under these conditions, unless an expert be in attendance the filters are not liable to develop their best and most uniform bacterial efficiency, and, besides, the use of coagulent cannot be economical. Furthermore, if the attendant should fail to close off the alum feed when the plant is shut down for the night, the solution would be emptied out of the tank during the night time into the suction well and a half dose of this chemical would be received into the institution. To counteract this possible occurrence the bidders propose, for the net sum of one hundred dollars, to install a coagulant feed pump and all appurtenances belonging thereto. This pump is to be actuated by the steam pump supplying water to the filters. Every stroke of the steam pump, whether running fast or slow, would cause the alum feed pump to also make a stroke and feed the required dose of coagulant—if the pump supplying the filters stops, so will the alum feed pump, and there will be no waste of coagulent. This apparatus will feed the coagulent solution uniformly at all times and in direct proportion to the volume of water supplied to the filters, and as the pump has a variable stroke it can be quickly and easily adjusted to feed varying quantities of the coagulent solution according to the condition of the river. Tables and scales, comprehensible by the most ignorant, showing how to mix and feed the coagulent in definite proportions, accompany the outfit.

The present subsidence capacity is in the neighborhood of one and a half hours and with two additional filter units it will be about three-quarters of an hour.

The plant is unfortunately located right on the bank and adjacent to the pump house, so that there is a limited area. One subsidence tank of the present capacity is too little to give efficiency where the filter unit is to be run up at a high rate, and, therefore, it argues in favor of more filter units in which to distribute the work of water purification at reduced rates of filtration.

Furthermore, with a high service pumping engine of nine hundred gallons per minute, it stands to reason that the filter plant should have at least this capacity under all conditions and at all times where the filtered water basin has a limited

capacity as in this instance. If the high service pump be operated at its full capacity of nine hundred gallons per minute, which is the economical rate to operate it, the filtering area should be sufficient to deliver a purified water at this rate.

The present filter units should not be operated in excess of five hundred and fifty-two gallons per minute. The three filter units like the present ones would deliver seven hundred and seventy-eight gallons per minute and four filters would deliver nine hundred and four gallons per minute. If two filters of the make proposed by the bidders, each thirteen feet in diameter, were installed in connection with the existing filters, the plant would have a total filtering capacity of one thousand and eighty gallons per minute, or more than enough to keep the large pump supplied.

This is the best proposal submitted, which is Proposal "E." With this capacity of filtration it is not necessary, to extend the filtered water well.

The improved method for applying the coagulant solution should be adapted.

The filtered water well or pump well for the high service pump is not covered with a floor. Water from leaky stuffing boxes or valves or leakage of water, through staves of the filter tank, or raw river water slopping over from the filter can fall into the filtered water below and contaminate it, thus spoiling all results of filtration. In a modern well designed plant this danger is eliminated by the construction of a water-tight floor underneath the filters forming an impervious roof to the filtered water well. This improvement should be made without fail over the existing filtered water basin and a pitch should be given to the surface of the floor and the drainage be conducted to the sewer.

The design submitted is an advancement over the plan approved under the permit of August fourteenth, nineteen hundred and eight, in that it provides for two filter units instead of one and in that it affords an automatic arrangement of improved design for the feeding of the coagulant solution to the raw water.

It has been determined that the proposal for two additional thirteen foot filter units, without additional storage of filtered water, and that the proposal for the improved coagulant feed, in conformity with the plan submitted, will not be prejudicial to the public health if adopted by the Board of Trustees, and the plans therefor are hereby and herein approved and a permit issued, under the following conditions and stipulations:

FIRST: The improvements shall be made in conformity with these plans and thereafter the plant shall be operated in an efficient manner, satisfactory to the Commissioner of Health. Daily reports of the operation of the water works system shall be kept on blank forms satisfactory to the State Department of Health and copies thereof shall be filed in the office of the Commissioner of Health.

SECOND: It is the purpose of the State Department of Health to collect samples of the raw water and the filtered water and to watch the operation of the system, and if at any time, in the opinion of the Commissioner of Health, the plant or any part of the water works system is prejudicial to public health, then such remedial measures shall be adopted as the Commissioner of Health may suggest or approve.

THIRD: The Board of Trustees shall provide adequate and duplicate pumping machinery for the raising of raw river water into the filter plant and attention is called to the suggestions hereinbefore made relative to this point.

FOURTH: The Trustees shall prepare an accurate detail plan of the existing pumping station and lay-out, including the intake pipe, the run nearby, the railroads, adjacent buildings, location of valves and force main, and file the same in the office of the Commissioner of Health on or before the completion of the filter unit herein approved.

FIFTH: The Board of Trustees shall build a concrete water tight floor over the present filtered water well and this shall be done and completed at the time that the two additional filters herein approved shall be completed.

SIXTH: This permit is issued under the express stipulation that the work herein authorized and approved shall be done during the current season.

It would appear from the evidence at hand that an examination of the intake pipe at the river and leading therefrom to the receiving well on the flats should be carefully made by some qualified expert in the employ of the Trustees. Probably defects in this line may be found and remedies applied, whereby an ample quantity of water may be assured at all times at the pump well and raw water feed pumps.

Harrisburg, Pa., August 24th, 1908.

DANVILLE, MONTOUR COUNTY.

Danville State Hospital for the Insane.

This permit was issued to the Board of Trustees of the State Hospital for the Insane at Danville, Montour county, relative to certain proposed improvements to the water works system of the institution as provided for by law. The approval of the plans and the permit herein are under certain conditions and stipulations hereinafter appearing.

Mr. R. Scott Ammerman, solicitor for the Board, on September twenty-ninth, nineteen hundred and eight, submitted a proposition from the water filter company whose plans were approved by the Commisioner of Health in due form in a permit issued August twenty-fourth, nineteen hundred and eight. The letter of the water filter company to the Superintendent of the institution is given in full below:

"September 22, 1908.

"Dr. H. B. Meredith,

"Supt. State Hospital for the Insane,

"Danville, Pa.

"Dear Sir:—Agreeable to the understanding had at the last meeting of your Executive Committee, we are handing you herewith, in duplicate, our proposal, as originally submitted under date of August 11th, 1908, but omitting therefrom our several other proposals which are not now to be considered, and including only such portions as relate to the work actually to be done in accordance with the permit issued by the State Department of Health and the decision of your Executive Committee.

"The enclosed redraft of proposal, you will find, is copied almost verbatim ad literatum from our original proposal, excepting that we have included therein the additional items of installing a new low service pump, putting in a new coagulant feed pump, covering your existing filtered water basin with a concrete floor, and covering the strainer on river end of intake pipe. In our new specifications we have also covered a description of the extra work which we are now asked to perform.

"The price named in our redraft of proposal is made up as follows:

"Our price for two filters 13 feet diameter per our proposal "E" of Aug. 11, 1908, ...	$5,889 00
"Less deduction allowed for omission of filtered water basin beneath filter house extension, per our proposal "C" of Aug. 11, 1908, ...	506 00
	$5,383 00
"New coagulant feed pump, per letter accompanying our proposal of Aug. 11, 1908, ...	100 00
"New Worthington low service pump, per our letter of Aug. 14, 1908,	1,050 00
"Covering the existing filtered water basin with a concrete floor, ...	450 00
"Stone covering for strainer on river end of intake pipe, ...	200 00
	$7,183 00

"The trouble with your intake pipe is that the aggregate cross sectional area of the perforations in the strainer on the river end is too limited, being equal to about 44 square inches, whereas the area of the 16 inch intake pipe is 201 square inches. As nearly as the writer could determine, the strainer on the river end of intake contained about 400 holes about 3-8 inch diameter. During high stages of the river it is more than likely that these perforations become obstructed with gravel or particles of coal. This condition can be relieved by covering the existing strainer with broken stone, as shown on our drawing No. 15-F-1, and as described in our proposal and specifications, as the stone would prevent access of coal and gravel to the perforations while the voids would be ample to allow free ingress of water. As your low service pump suction pipe is 8 inch diameter and has a cross sectional area of 50 square inches, you will see that the 44 square inches of perforations in strainer on river end of intake are not equal to the area of the suction pipe to low service pumps.

"A better and more permanent method of correcting trouble with the intake pipe would be to cut off the end of present strainer and slip over this pipe a cast iron strainer substantially as shown on our drawing No. 14-F-1. Our redraft of proposal, as enclosed herewith, contemplates our covering the existing strainer on river intake with broken stone only. If you should conclude to have us put on the new cast-iron strainer shown on our drawing No. 14-F-1, $200.00 must be added to our price of $7,183.00.

"If we are to do the work on the intake pipe it is important that the contract be signed up without delay so that we can take advanage of the present low stage of the river, as our estimates are based on our being able to do this work while the river is low. If you should conclude to have us supply the new strainer casting shown on our drawing No. 14-F-1, we would thank you to wire us as soon as this decision is reached so that we can order the patterns and castings immediately and get the work in with the least possible delay and while the river is low. If this new strainer casting is used we could cut off the blank end of your present strainer and leave end of pipe open. The perforations in our strainer, which are on the side walls only, would have area equal to area of the 16 inch pipe. We would anchor this new strainer in place so that it could not be disturbed.

"Covering the existing filtered water basin with a concrete floor, and making alterations to intake, are not easy tasks, and as costs will depend largely upon conditions existing at the time the work is done. If the river should be high when

we do work on the intake the extra precautions to be taken would soon eat up the little profit included in our figures. In covering your filtered water basin we would have to do the work so as not to interfere with the operation of the plant.

"We hope the matter is now in such shape that contract can be drawn up and duly executed with little delay. If matters can be expedited in any way by another meeting of your Executive Committee with the writer, the undersigned will be glad to be in Danville any day and hour you may name. We are particularly anxious to get at the intake at once if we are to do this work.

"Awaiting your further commands, and hoping you will find the enclosed redraft of proposal and specifications satisfactory, and that you will notify us promptly if they are not, we remain,

"Very truly yours,

"AMERICAN WATER SOFTENER CO.,

By Geo. F. Hodkinson,

Mgr. Filter Dept."

"GFH—MP.

The plans for the improvements to the intake have been submitted and filed in the office of the Commissioner of Health. Their execution involves a total expenditure of two hundred dollars in addition to the total bid of seven thousand one hundred and eighty-three dollars.

It has been determined that the proposed plans are not prejudicial to public health and the same are hereby and herein approved and a permit issued therefor.

The improvements to the intake are called for by the following clause of the said permit of August twenty-fourth, nineteen hundred and eight:

"It would appear from the evidence at hand that an examination of the intake pipe at the river and leading therefrom to the receiving well on the flats should be carefully made by some qualified expert in the employ of the Trustees. Probably defects in this line may be found and remedies applied whereby an ample quantity of water may be assured at all times at the pump well and raw water feed pumps."

The item for the concrete water-tight floor is required by the Fifth Condition of the said permit of August twenty-fourth, nineteen hundred and eight, as follows:

"The Board of Trustees shall build a concrete water-tight floor from the present filtered water well and this should be done and completed at the time that the two additional filters herein approved shall be completed."

The items for additional pumping machinery were called for in the Third Condition of said permit, as follows:

"The Board of Trustees shall provide adequate and duplicate pumping machinery for the raising of raw river water into the filter plant and attention is called to the suggestions hereinbefore made relative to this point."

Harrisburg, Pa., October 20th, 1908.

DERRY TOWNSHIP, DAUPHIN COUNTY.

Hershey Village, M. S. Hershey.

This application was made by Mr. M. S. Hershey, of Hershey Village, Derry township, Dauphin county, and is for permission to extend his water works system for the supply of water to the public in the village of Hershey and to obtain an additional source of supply therefor.

Act One hundred and eighty-two, approved April twenty-second, nineteen hundred and five, provides that an individual supplying water to the public shall not extend the water works or obtain an additional source of supply without a written permit to be obtained from the Commissioner of Health.

It is represented by the petitioner that he is the individual owner of the water works now supplying water in the village of Hershey and vicinity. This village is in Derry township on the Philadelphia and Reading Railway, fourteen miles east of Harrisburg. A large area of ground about three-quarters of a mile square was purchased about four years ago by Mr. M. S. Hershey and he at once laid it out into streets and established a plant for the manufacture of chocolate, which is operated under the name of M. S. Hershey Chocolate Company. He also built a number of houses for employes and a bank and a school house and fire house and a water works system to supply water to the factory and to anyone who might care to buy the water. The factory and all the other main buildings are substantial stone structures. In addition to these improvements Mr. Hershey built a trolley line and an amusement park for the accommodation of the villagers. The inhabitants depend exclusively on the chocolate factory for their support, there being no other industry in the vicinity. Hummelstown is about three and one-half miles to the west and the village of Palmyra is about three miles to the east. The country round-about is open rolling farming land. In the village there is a population of about eight hundred.

It is reported that there are cesspools in use at fifty dwellings and that at other estates not connected with the sewers privy vaults are provided. The geological formation is limestone.

Through the central part of the village in a westerly direction flows Spring Creek, a stream which rises about three miles easterly and empties into the Swatara Creek nearly two miles westerly opposite the village of Union Deposit. The railroad, factory and major portion of Hershey lies south of the creek, but there is in the north-eastern corner of the village a short stretch of the railroad north of the creek and it is in this part along a main tributary of the creek east of the railroad that the new supply of water is to be obtained. On the hill east of this tributary is Mr. Hershey's mansion, and there is a private sewer from it southerly to the main creek. It is a pipe sixteen inches in diameter.

Down stream eight hundred feet at the railroad culvert there is a twenty-four inch sewer into the creek. It is six hundred feet long and conveys all the factory sewage and waste to the stream. The waste is principally rinsing water from milk cans. This sewer is less than one hundred feet down stream from the water works pumping station.

The next sewer is ten inches in diameter, it conveys the drainage from the school house, hotel, bank, fire house and railroad station, northerly under the railroad embankment to an open ditch which extends northerly through the field passing within sixty feet of two dwellings a distance of two hundred feet to the creek. The point of discharge is eight hundred feet below the railroad culvert.

The last two sewers mentioned appear to have been established when the buildings were erected. The sewer from the Hershey mansion is of recent construction and has not yet been used since the dwelling has not yet been occupied.

There are upwards of ninety dwellings in the village and about two-thirds of them are furnished with water supplied from Mr. Hershey's pipe lines. The other houses obtain their drinking water from private wells drilled on the premises. The waste water from these buildings is disposed of principally into cesspools from which the water percolates through the soil or passes off in crevices through the limestone rock. In a number of instances sewage is emptied into these cesspools. Earth privy vaults boarded up or lined with loose stone work are generally used for the reception of excrement.

The source of supply of Mr. Hershey's water works is a spring at the foot of the hill on which the factory is located. Before the railroad embankment was built there the water flowed out over the fields northerly about one hundred feet to Spring Creek. Now the said embankment is over the spring and the water is piped through a twenty inch pipe to the northerly edge of the embankment where there is constructed a concrete receiving well seven feet square and ten feet high roofed over with a hinged cover on top kept locked. Seven feet of this structure is above ground and two feet from the top there is a six inch overflow pipe. Near the bottom there are also two six inch overflow pipes one of which is kept plugged. The other extends out a few feet from the well and is brought to the surface of the ground or thereabouts and its end is approximately three feet above he bottom of the well. Therefore, the spring water will overflow from the well when the depth in the well exceeds about three feet. On the day of the Department's inspection, February twenty-eighth, nineteen hundred and eight, when Spring Creek was in flood, the lower overflow was submerged several inches by the flow so that if the draft upon the spring water had been greater than the flow, through the twenty inch pipe into the well, Stony Creek water would have entered through the overflow pipe into the well and been introduced into the water works system. In fact, however, on said date the water was sufficiently high in the well to overcome the head over the overflow pipe and so it passed out into Spring Creek.

Into the well there is inserted a six inch suction pipe. This line is laid northerly along the bottom of the railroad embankment to the railroad culvert and thence in the bed of the creek up stream through the culvert, a total length of about three hundred feet to the pumping station which is located near the south bank of the creek east of the railroad. This suction pipe is directly connected to two pumping engines electrically driven, each being a triplex, vertical, single-action pump rated at one hundred and fifty thousand gallons capacity daily. The water may be forced through either one of two pipes six inches in diameter, four hundred feet long to an iron tank located on the hill, back of the factory having a diameter of eighteen feet and a depth of twenty-seven feet. The high level in this tank is reported to be one hundred feet above the pump house floor and about fifty feet above the centre of the town. The storage capacity of the tank is fifty thousand gallons. It is reported that the pumping engines by an arrangement of valves can force water directly into the street mains. These pipes comprise about one half mile of six inch and about one and a half miles of four inch mains. Fire hydrants are attached to the distributing system at convenient points.

The average daily consumption is one hundred and forty thousand gallons, so stated, of which twenty-five thousand gallons are estimated to be used for domestic purposes. This consumption plus the increased demand which might be made upon the water system at any moment in case of fire would tax the present source and pumping machinery beyond their capacity. The petitioner purposes to obtain an adequate supply and to install additional machinery capable of meeting all demands.

At the foot of the hill where the Hershey mansion is located, out of a crevice in limestone rock, gushes forth a large volume of ground water measured to be at the rate of two million gallons per twenty-four hours minimum flow. This large quantity evidently is not of local origin. Probably it is collected from an extended area of sparsely settled farming territory.

The spring discharges into a storage basin irregular in shape and in the neighborhood of five hundred feet long built between the bottom of the hill and the run, whose water level is to be three and one half feet above the bank of the run. Details of this reservoir have not been submitted, neither have plans of the proposed supply main and improvements at the pumping station. A concrete dam about five feet high and one hundred and fifty feet long at the lower end of the basin and an earth embankment lined on the inner side with a dry rubble masonry wall five feet in height extending up stream near the run and finally terminating at the hillside, together with said hillside excavated at the bottom and walled up to a height of five feet forms the enclosure for the impounding of the spring water. On February twenty-seventh, nineteen hundred and eight, evidences were seen of the overflow of the creek or run into the basin over the embankment at the upper end of the basin.

From this reservoir an eighteen inch pipe extends down the run valley crossing a public highway and spring creek, a distance of about five hundred feet to the new pump well built at the pumping station.

This well is nine feet in diameter, fourteen feet deep, is made of concrete, is covered with boards and the top is about six feet above the surface of the ground. The height of water at the reservoir is nine feet above the bottom of this new pump well so that an abundant supply of water is always assured at the well. It would appear that there is no means of contaminating the water in this well, provided the entrance of the eighteen inch pipe through the walls into the well be thoroughly protected and secured against leakage at times when for any cause the well should be emptied.

The pumping station has been enlarged, a steam boiler plant has been erected and a horizontal duplex steam pumping engine installed. The rated capacity of the latter is one million five hundred thousand gallons per twenty-four hours. A twelve inch suction pipe extends from the pump to the new pump well.

So it appears that the new water works improvements will give good manufacturing, domestic and fire service to the town.

Chemical analysis of the water show it to be of medium hardness, as will be expected from a limestone region. The topography of the country would indicate that the contributing area to the supply lies between Spring Creek and its main tributary above mentioned, which is sparsely populated. With due care, exercised at the farm houses on this area and at the Hershey mansion, respecting sewage disposal there should be no organic pollution of the spring water. But this conclusion does not follow with respect to the spring at the foot of the railroad embankment and now used as a source of supply to the village. It might be possible for cesspool drainage from the village houses to contaminate this source or the private well supplies. A systematic test of the quality of these private supplies should be made and if found to be polluted they should be abandoned.

The existing source of supply of the water works should also be abandoned when the new supply is ready for use. It is apparent that if on February 27th, both pumping engines had drawn down the water in the old pump well that the creek water would have flowed into the well so that the sewage from the factory, in this event, might have been supplied to the water consumers in the borough. This, of course, is on the assumption that the flow of the spring at the time was less than the combined capacity of the two pumping engines. But apart from the possibility of sewage pollution of the well water from the surface sources, is the ever present menace of underground pollution of the spring itself which, in the interests of public health, warrants the abandonment of the supply.

Unless the petitioner can show good reasons for the continued use of said old supply, it should be entirely disconnected from the water works system.

At least monthly bacteriological tests of the proposed new supply should be taken.

At Hummelstown borough the Swatara Creek furnishes the water supplied to the citizens of that town for domestic uses. The discharge of sewage into Spring Creek, is therefore, a great menace to the health of the public in Hummelstown. This fact has evidently been overlooked by those in Hershey village who now discharge sewage into Spring Creek.

In view of these considerations, it has been determined that the proposed source of supply will not be prejudicial to the public health and a permit is hereby and herein granted therefor and for the extension of the water works system in the village of Hershey, under the following conditions and stipulations:

FIRST. That upon the introduction of the water from the new source of supply into the distributing pipe system of the village, the owner thereof shall disconnect the old existing source of supply and abandon its use, provided, however, that it may be maintained as an emergency supply if the said owner can show reasons therefor satisfactory to the Commissioner of Health.

SECOND. The owner shall cause to be made monthly bacteriological tests of the new source of supply and shall file copies thereof with the Commissioner of Health. If at any time in the opinion of the Commissioner of Health the said

source of supply or the water works system or any part thereof, has become prejudicial to the public health, then such remedial measures shall be forthwith adopted as the Commissioner of Health may approve or advise.

THIRD. This permit is granted under the express stipulation that on or before June first, nineteen hundred and eight, detail plans and elevations of the storage basin, pump well and station, standpipe and water works, showing all pipes, valves, and so forth, shall be prepared and filed in the office of the Commissioner of Health. And at the close of each season's work, a plan of all additional street mains laid during the year, together with any other information in connection therewith that may be required, shall be filed in the office of the Commissioner of Health, to the end that the State may have complete information of the extent of the water works system and its use by the public.

FOURTH. The owner shall raise the embankment above the storage reservoir at the upper end to a sufficient height to prevent the overflow of surface waters into the basin and all surface water shall be excluded from the basin. Precaution shall be taken to keep all animals out of the basin.

FIFTH. On the land immediately adjacent to and higher than the neighborhood of the storage basin and the spring emptying into it, there shall be no discharge of sewage into or onto the surface of the ground or into any receptacle from which the sewage may overflow or percolate. The sewer from the Hershey mansion now discharging into the creek shall be discontinued or the same shall not be used and sewage discharged therefrom into the waters of the State. The art of treating sewage to destroy all pathogenic matter therein has sufficiently developed to render feasible the installation of disposal works to accomplish this purpose before the liquids flow into any stream.

The owners of the several sewers now discharging directly or indirectly into the stream in Hershey village, will be ordered by the Commissioner of Health to discontinue such discharge. Probably the devising of an intercepting sewer and a common sewage disposal plant for the treatment of the sewage from the sewers and from those which may be built in the village in the future would be the most economical and satisfactory solution of the problem. The Department will be glad to advise further with respect to this matter.

The Department will also cause an examination of individual well waters to be made.

Harrisburg, Pa., March 10, 1908.

EDDYSTONE, DELAWARE COUNTY.

Ridley Water Company.

This application was made by the Ridley Water Company of Eddystone borough, Delaware county, and is for permission to install a system of water works for the supply of water to the public in said borough.

The Ridley Water Company is a corporation duly organized under the laws of the State. Its charter was approved June seventh, one thousand nine hundred and seven, having been recommended by the State Water Supply Commission with the understanding that the source of supply was to be the Delaware River, the water to be furnished at the boundary line between the city of Chester and the borough of Eddystone by the New Chester Water Company.

The borough of Eddystone is located on the north bank of the Delaware River and adjoins the city of Chester on the up stream side, the two municipalities being separated by Ridley Creek. The eastern boundary of the borough is Crum Creek, a stream which rises back in the hilly portions of the county and drains a rather sparsely populated territory, more especially in its upper parts.

Until recently, Eddystone was unprogressive. Since the establishment of several large manufacturing plants in the borough a boom has occurred. Among the important industries may be mentioned the Eddystone Print Works, employing about fifteen hundred hands, the Baldwin Locomotive Works, employing about the same number, the Belmont Iron Works and the Tindel, Morris & Company Saw Works.

Besides having a tide water river front (the main channel of the river being near the borough shores), the main line of the Pennsylvania Railroad between Philadelphia and Washington, the Baltimore and Ohio, and a local branch of the Philadelphia and Reading Railway pass through the town. The land is flat and low but drains naturally towards the two creeks and the river, there are extensive and favorable manufacturing sites unused, local taxes are low and prospects appear bright for a future community of considerable size. In nineteen hundred the population was seven hundred and seventy-six. Now it is estimated to be fifteen hundred.

There are a number of dug wells at the existing residences, but the majority of the inhabitants are supplied with public water furnished by the Eddystone Water Company.

The Eddystone Water Company was chartered on December twenty-second, eighteen hundred and ninety-two, for the purpose of supplying water to the public in the borough of Eddystone, Delaware county. It immediately proceeded to construct water works and to supply filtered water to all the residents in the borough

who care to purchase the same. This water comes from Crum Creek, is filtered and is furnished by the Springfield Water Company to the Eddystone Water Company, which Springfield Water Company operates the Eddystone Water Company's works.

On the creek in Springfield township about five miles above Eddystone, there is a dam and pump house. Above this point there are about twenty-eight square miles of water shed rural in character. The pumps lift the water to a nearby sedimentation basin from whence it is forced through pressure filters to Marple Hill reservoir. From this reservoir the water flows by gravity to the consumers. The water in the reservoir is about two hundred and fifty feet above Eddystone borough. The pressure in the mains at the latter place is said to average about eighty pounds. A twelve inch main reduces to eight inches at the borough line and this pipe connects with six inch and four inch laterals laid in most of the streets of the borough. Fire hydrants are placed at important street corners.

The water company supplies about one-half of the residences and it furnishes some water to each industrial plant.

A defunct company having the name of Eddystone Water Company was chartered April nineteenth, eighteen hundred and eighty-seven, for the purpose of furnishing water to the public in all that certain portion of Ridley township, in Delaware county, lying south and west of Crum Creek and bordered by said Crum Creek and by Ridley Creek and the Delaware River. The control of this company was effected by the New Chester Water Company in eighteen hundred and ninety-one. The latter company immediately laid eight lengths of eight inch pipe on Ninth street in Eddystone, but no connections with the New Chester Water Company's mains were made or water furnished. Since that time no further work has been done, so the charter lapsed. On the record books in the Secretary of State's office appears a transaction between the New Chester Water Company and the Eddystone Water Company in nineteen hundred and six, whereby the latter is represented as having sold and transferred its franchise and property to the former. Since such franchise long since lapsed, the New Chester Water Company does not thereby possess territorial rights in Eddystone borough.

The New Chester Water Company draws its supply from the Delaware River opposite the city of Chester at a point where the sewage from said city and from Philadelphia has an opportunity to pollute the water. Pumps raise the supply to reservoirs and a purification plant located back on the hills north of the city. Here by sedimentation, coagulation and filtration, the raw water is supposed to be sufficiently purified to render it safe for drinking purposes. It is then returned and supplied to the inhabitants of Chester city, Upland borough and Lower Chichester township. There are a few water takers in Chester township.

The petitioners purpose to connect a twelve inch pipe at the Ninth Street bridge over Ridley Creek with a twelve inch connection in said street in the city of Chester leading to the twenty-four inch supply main from the purification plant.

The petitioners state that it is proposed to lay between two and three miles of street mains in Eddystone, that there will probably be between two and three hundred taps, but are unable to say what the classification of the takers will be. However, a minimum consumption of one million gallons daily and a maximum of double this amount is estimated and stated in the application.

At the Baldwin Locomotive Works there is an artesian well forty feet deep which supplies water for boiler purposes. In addition to this possibly five million gallons per month is purchased of the Eddystone Water Company for drinking purposes. It appears that the Eddystone Water Company's supply to said works is ample in amount, satisfactory in quality and the rates are reasonable. So unless special inducements are offered by a new company the existing water company may continue to furnish water here.

The Eddystone Print Works pump water from the Delaware River, using, so it is reported, nearly four million gallons per day.

The Belmont Iron Works, recently completed, may buy its water from the company which offers the lowest rate.

Whether the Ridley Water Company purposes to afford fire protection is not known to the Department. The plans submitted do not indicate whether there are to be facilities for the ready drainage of the water pipe system. The sizes of the water pipes are not shown, so that the Department cannot tell whether reasonable and customary safeguards to public health are intended or have been provided for.

If it be true that the Ridley Water Company is to make a demand of the New Chester Water Company for a maximum of two million gallons daily, when the New Chester Water Company's filter plant is in danger of proving inadequate in capacity to meet the total demand. So additions would have to be made.

Furthermore, because the raw water is dangerous and in case of carelessness or negligence at the filter plant, poisonous matter in the supply at its source might be transmitted to and delivered into the water pipes and thence to the consumers in the Ridley Water Company's district, the latter company should have some agreement whereby it can hold the New Chester Water Company responsible, and assure to itself and its consumers a constantly pure and wholesome supply of water.

If the New Chester Water Company will operate its purification plant in a manner and purify the water to the satisfaction of the Commissioner of Health and the Ridley Water Company can secure an agreement to such a stipulation, then the Commissioner of Health would be warranted in determining that the proposed supply would not be prejudicial to public health.

In view of these circumstances, it has been determined that the proposed water works system and the supply therefor for the borough of Eddystone by the Ridley Water Company will not be prejudicial to public health, and a permit is hereby and herein granted therefor, under the following conditions and stipulations:

FIRST. This permit shall not be operated until the Ridley Water Company shall have entered into an agreement with the New Chester Water Company, whereby the latter shall guarantee to furnish the former with a sufficient quantity of water, the purity of which shall be satisfactory to the State Commissioner of Health. Tests of this water shall be made by the Ridley Water Company every two weeks and copies thereof shall be filed in the office of the State Department of Health. A copy of said agreement shall also be filed in said office.

SECOND. Before the Ridley Water Company shall lay any water pipes and use the same, plans thereof showing the location of pipes, valves, hydrants, blow-offs and drainage facilities, shall be filed in the office of the State Department of Health and be approved. Adequate facilities for quick drainage of the pipe system shall be afforded and be clearly designated on the plans. At the close of each season's work a plan of the water mains laid during the year shall be prepared and filed in the office of the Commissioner of Health, together with any other information in connection therewith that may be required, to the end that there shall be a complete record in said office of the extent of the works belonging to the Ridley Water Company and the number of people in said township dependent upon such supply.

THIRD. If at any time in the opinion of the Commissioner of Health the water supply or the water works, or any part thereof, has become prejudicial to public health, then the Ridley Water Company shall adopt such remedial measures to protect the public health as the Commissioner of Health may approve or suggest.

FOURTH. Regular inspection will be made of the Ridley Water Company system and supply by a Department officer. The Commissioner of Health may suggest rules and regulations to govern the supply of water to the public in so far as the public health is concerned. Said water company shall conform to orders, rules or regulations of the Department in so far as they may relate to the supply of water to the public in Eddystone borough.

FIFTH. This permit is issued under the express stipulation that the operations of the Ridley Water Company shall be wholly within its charter rights.

Harrisburg, Pa., March 24, 1908.

ELLWOOD CITY, LAWRENCE COUNTY.

Ellwood City Water Company.

This application was made by the Ellwood Water Company of the borough of Ellwood City, Lawrence county, and is for approval of plans for the enlargement of its plant and for an increase in the source of supply to the public in said borough.

On April twenty-ninth, nineteen hundred and seven, the Commissioner of Health issued a decree to the Ellwood Water Company withholding approval of the plans for a proposed extension of the water works system by the enlargement of the reservoir or storage basin to a capacity of four million gallons. The important clause in the decree was as follows:

"In view of the circumstances, I therefore withhold approval to the plans of the proposed extension of the water works system until plans for the purification of the sources of supply, or some other project for the furnishing of a pure and wholesome supply to the public in Ellwood City borough and vicinity be submitted to the Commissioner of Health for approval."

On June eighteenth, nineteen hundred and seven, the Ellwood City Board of Health inquired if it were necessary for the company to have a permit for locating the reservoir, and if so, whether the Ellwood Water Company had obtained such permit, with especial reference to the location of the structure near the cemetery; and on June twenty-seventh, the said local board requested the Commissioner of Health to have an inspection made of the reservoir being built by the water company, and to explain the stipulations of the decree issued by the said Commissioner to the said water company. Whereupon, the Department made such inspection of the complete plant.

The water works system is now operated by two pumping stations: One is in the power house of the Pennsylvania Power Company, taking its supply from the Connoquenessing Creek at the dam and delivering such water mainly to the Shelby Tube Company. The other station is on the bank of Slippery Rock Creek just above its junction with the Connoquenessing Creek. There is a one and one-half million gallon capacity pumping plant here delivering the Slippery Rock Creek supply to private consumers and to manufacturing plants in the town, through a ten inch force main and branches. The surplus daily pumpage had formerly gone to the smaller reservoir, whose enlargement was in progress at the time of the Department's inspection.

In the recent petition of the Elwood Water Company, the one now under consideration, it is stated that "the surplus daily pumpage is stored in a six million gallon storage reservoir."

The Connoquenessing Creek on the south bank of which Ellwood City borough is located, drains a water shed of about four hundred and twenty-five square miles and on it are the boroughs of Butler, Harmony and Zelienople, besides smaller places and hamlets.

The Slippery Rock Creek which discharges into the Connoquenessing about one mile above Ellwood City borough, has a drainage area of about four hundred and thirty-seven square miles. This area is much less populated than the Connoquenessing but nevertheless, sewage is discharged into it, particularly at Grove City borough and Slippery Rock borough. The Commissioner of Health has taken action with respect to compulsory sewage purification works at Butler and Zelienople and Grove City, and the work of preserving the purity of the waters of this shed for the protection of public health will continue to be prosecuted with due diligence.

The Slippery Rock pumping station is on the south bank of the creek at the forks of this stream and the Connoquenessing. Power is furnished by an electric motor of one hundred and eighty-five horse power which operates an electric centrifugal pump of one and one-half million gallons per twenty-four hours. The intake is a ten inch pipe extending twenty feet into Slippery Rock Creek, the outer end being closed and pipes perforated.

The ten inch rising main from the pump house extends westerly across private property a distance of over eight thousand feet to the junction of a twelve inch rising main which receives the water from the Connoquenessing Creek pump house at the dam.

At this time it is a considerable structure built to furnish power to run an electric power plant. There is a turbine water wheel operating a Gould pumping engine which forces the water through the said twelve inch main into the pipe system of the town at the point where it meets the ten inch main from the Slippery Rock pumping house. This rising twelve inch main passes by and through the plant of the Shelby Tube Company and supplies most of the water to said company.

There is also a four inch rising main from the Connoquenessing pumping station which supplies the central district of the town between the Connoquenessing Creek and the Baltimore and Ohio Railroad according to plans, which are not sufficient in detail to show location of valves and gates.

From the junction of the ten inch and twelve inch mains, water is taken through a ten inch line paralleling the Baltimore and Ohio Railroad to Fourth Street and its branches radiate through the town.

The reservoir as originally constructed was very small and consisted of an excavation in the hillside back of the borough. There was a dirt dam constructed below the earth excavation to hold the water. The new reservoir of six million gallons capacity as reported, and constructed by the water company without approval of the Commissioner of Health, is located about one hundred and ninety feet, vertical height, above Fourth and Spring Streets in the borough. A large excavation was made in the side of the hill sufficient to form the embankment on the lower side to complete the basin, the said embankments or dam being provided with a core wall of concrete masonry, so it is reported.

Furthermore, it is reported that the interior sides and bottom of the reservoir were to be lined with concrete varying from four to six inches but this has not been done.

About two hundred feet back of the reservoir and between fifty and one hundred feet higher there is a cemetery containing thirty-five graves along that portion of the ground where it slopes directly to the reservoir. The geological formation to a depth equal with the bottom of the reservoir, is first, ordinary soil; second, clay; third, loose shale; fourth, a thirty inch outcrop of coal, and below this coal, fire clay.

The citizens of the borough and the local board of health have been considerably exercised as to the possibility of the drainage from the cemetery and from the graves located therein reaching the water in the reservoir, and it would seem as though these fears had some foundation unless the reservoir is thorough lined with some water proof substance material and further protected by a drainage ditch around its upper sides and between it and the cemetery.

The waters of the two sources are extremely turbid quite frequently. The quality of the Slippery Rock Supply is said to be preferable on this account, to the other stream at nearly all times of the year, but even the water from the better supply is often roily and turbid and has a bad odor and taste. The Department is reliably informed that the officers of the Ellwood Water Company and those citizens of the borough who can afford to do so, purchase water for drinking purposes from persons engaged in business of bottling spring water and selling it.

The water company supplies about thirty-six hundred people in the borough and one thousand outside of the borough. There are about fifty driven wells in the town which are used by the private owners of the property. The average consumption of public water for manufacturing purposes is about four hundred and fifty thousand gallons daily and for domestic purposes about five hundred and fifty thousand gallons, making a total average consumption of one million gallons daily. There are a few dead ends in the water line.

With respect to the public health it has been ascertained that much of the sickness is charged up against the public supply of water. At the time of the Butler typhoid epidemic, it is reported that there were a higher number of typhoid cases in Ellwood City than at any time before or since.

On September thirteenth, nineteen hundred and seven, the borough board of health requested the State Board of Health to see that the water company's reservoir was cemented on the sides and bottom.

The following communication was sent by the Commissioner of Health to the water company on September thirteenth, nineteen hundred and seven:

"I beg to call your attention to the fact that the security of your investments in the water works of Ellwood City depends to quite a degree, upon your compliance with State laws, and that the terms of the decree issued to you in April of this year have not yet been complied with. I call your attention to this, and urge you to be prompt and not further delay compliance with the request of the State."

On November twenty-third, nineteen hundred and seven, the water company notified the Commissioner of Health that on account of the unsettled financial condition, it was forced to abandon for the present the carrying out of the plans for a filtration plant. In the letter was the following statement: "The matter was fairly well under way when the condition of the money market became such that we were obliged to postpone for the present any future work." In answer to this the Commissioner of Health sent the following letter on November twenty-nine, nineteen hundred and seven:

"Samuel A. Roelofs, President,
Ellwood Water Company,
"Ellwood City, Pennsylvania.

"Dear Sir:

"In reply to your esteemed favor of November twenty-third, saying that you have abandoned, for the present, carrying out plans for filtration plant, I beg to say that such an abandonment does not relieve you from the responsibility of supplying a pure water to the people of Ellwood City. You know your sources of supply to be impure and dangerous. At any time it may poison the water consumers of Ellwood City. I have warned you and I do hereby and herein warn you, that your sources of supply are prejudicial to the public health, and if you do not take all reasonable precautions to warn the public of the danger and to safeguard public health so far as your water supply is concerned, you are rendering yourself financially and criminally responsible, to an extent possibly much greater than you have any idea of.

"What would you do in the event of an outbreak of typhoid fever in Ellwood City, and what ground would you have for defense?

"Your attention is again called to the subject of the requirements set forth in former communications from this Department to your water company.

"Yours very truly,"

On March twenty-eighth, nineteen hundred and eight, the company's experts communicated with the Commissioner of Health and among other things made the following statement:

"I desire to say that these plans for the new pumping station and filter plant are substantially completed and as soon as the same may be checked over, estimates and specifications prepared, and a report made to the water company, they will be ready for submission to your department which will probably be in about thirty days from this date.

"We originally expected to have these plans completed at an earlier date, but owing to the difficulty of securing funds, the destruction of the power company's plant on March first, which plant furnished the power to operate our present pumping machinery, we have been obliged to concentrate all our efforts toward temporary expedients to maintain the water supply in this district."

The said application of June first, nineteen hundred and eight, states, "owing to the probable increase in demands for waters and betterment of its supply, the company desires to extend its capacity and works by the construction of a new plant of six million gallons ultimate capacity, located on north side of Slippery Rock Creek with intakes into said creek."

The proposed plan is to comprise a new boiler and pump house, intakes, settling basins, filter plant, filtered water reservoir under the filter plant and all necessary appliances and appurtenances for modern water purification works of six million gallons capacity.

Plans in detail of construction are submitted but specifications and description of the intended operation of the plant have not been submitted presumably on account of the intention of the company not to erect the works at this time. The petition states as follows:

"The water company cannot raise funds until its existing bonds mature in August nineteen hundred and nine, and desires to have plans approved, that it may make estimates to finance cost so as to have plant completed by January first, nineteen hundred and eleven."

Owing to the fact that Slippery Rock Creek passes through an agricultural territory on which there are sources of sewage pollution, there is no time of the year when this source is not subject to accidental or direct pollution, and, therefore, until such time as the Ellwood Water Company shall filter the water from this source before it is delivered to the consumers in its district, the present complaints from citizens and physicians about the danger to public health will be well founded and

continued cases of sickness from water borne diseases may be expected. Because the Connoquenessing Creek supply is much more polluted by sewage, it should be absolutely prohibited as a source of public water supply without filtration, provided that it be possible to get water from any other source. It seems remarkable that there has not been more sickness among consumers when this supply was being used than has been reported. In fact it would not be surprising if at any time an epidemic of water borne disease should break out effecting a large portion of the inhabitants of the borough who use the public supply. The situation demands that the water purification plant shall be installed at the Slippery Rock source at once. The reason for delay offered by the company cannot be considered by the Commissioner of Health, the interests of public health are paramount. Human life cannot be placed in jeopardy because a private corporation is unable to fulfil its charter obligation to furnish to the public a pure and wholesome water.

There must be means found to provide the remedy.

Not only should the purification plant be constructed, but the reservoir on the hill should be lined with concrete masonry as originally planned, especially on the sides next to the cemetery and on the bottom.

Since the Ellwood Water Company have proceeded in defiance of law to extend its water works system by making additions thereto and has thus increased its source of supply to the public illegally and to the menace of public health to a greater or less degree, it has been determined that the said company shall and said company is hereby and herein notified that it shall on or before ninety days from the date of this decree, begin construction of the proposed purification plant according to detail specifications of the construction and operation of the same, to be submitted by said company to the Department of Health and approved by said Department, which approvals shall be accompanied by stipulated conditions under which approval of the source of supply and water works system may be given, and failure on the part of the Ellwood Water Company so to do shall be understood and deemed to be an admission of its inability to fulfil its charter obligations, and the Department of Health will so understand it and proceed accordingly in the interests of the public welfare; provided, however, that if satisfactory evidence shall be forthcoming that ninety days is too short a time in which to make such beginning in construction, then the Department of Health may extend the time but not for any longer period of time and then only when specified that the company will be able to carry out the terms of the decree in the immediate future.

The water company is hereby notified that the plans submitted for the new purification plant are in the main satisfactory and that when the specifications for the construction thereof and the description of the intended operation of the plant shall have been submitted, it is probable that entire approval of the plant may be given.

Harrisburg, Pa., August 5, 1908.

EMLENTON, VENANGO COUNTY.

Emlenton Water Company.

This application was made by the Emlenton Water Company, of Emlenton borough, Venango county, and is for permission to obtain an additional source of supply and to extend street mains.

Emlenton borough is a small residential community estimated to contain thirteen hundred inhabitants located in the oil fields on the north bank of the Allegheny River at the extreme southeast corner of Venango county. The size of the place has been nearly stationary for the last three decades.

The town site is partly on the slope of a mountain and partly on the flats or shelf of ground between the bottom of the mountain and the river. This low lying section is from twenty to fifty feet above the low stage in the river.

There is a municipal sewerage system to which is admitted both sewerage and storm water. The discharge is into the Allegheny River at a point in the lower part of the town. A very general use of this sewer system is made. However, there are numerous privies and shallow earth vaults in use. These are often in proximity to springs and dug wells from which water is drawn and used for domestic purposes.

The sewers were built in nineteen hundred and one and nineteen hundred and two. During the construction and immediately following it there was a marked increase in typhoid fever cases which was attributed by local physicians to the exposing on the streets of the excavations from the sewer trenches. These piles of earth contained, so it was thought, poisonous matter which had accumulated in the ground by percolations from privy vaults and household drainage. During the warm weather flies swarmed on the polluted soil thus excavated and may have carried infection into the homes and onto the foods consumed by the people residing in the vicinity. The outbreaks of the disease were in the localities where the excavations were being made.

In the fall of nineteen hundred and four, there were some thirty cases of typhoid fever and, according to meagre reports, an epidemic of diarrhoea and stomach troubles prevailed, extending into the following spring, during which fully one-third of the population in the borough was affected. It appears that sickness pre-

vailed among users of private and the public water supply. From such records as the Department has been able to obtain thus far it appears that there were seven cases of typhoid fever in nineteen hundred and five, nine in nineteen hundred and six, seven in nineteen hundred and seven and six cases during the first two months of nineteen hundred and eight. The evidence presented is that the disease has appeared in the homes of those using the private sources as well as those using the public sources.

Without doubt the contamination of the ground with sewage renders the waters of wells and springs located in the built-up part of the town extremely suspicious, to say the least, as a suitable supply for domestic purposes.

The Haggerty Spring is located under an old house. The water is collected in a stone-lined pool, covered over with plank and located under the house. This dwelling is not now occupied but was sometime since by a number of Italians. At that time it is said the conditions on the property were filthy. A number of years ago a perpetual lease was given for the use of the waters from this spring by certain neighbors. Pipes lead from it to several dwellings. Two samples of water were recently collected and analyzed by the Department. No sewage pollution was indicated by the tests.

The Gosser spring is in the centre of the town. There are neighborhood rights to its waters. Above the spring are several residences and privies. Two tests recently made of these waters did not indicate sewage pollution.

The public water supply is owned by the Emlenton Water Company. By an application for letters patent filed in the office of the Secretary of the Commonwealth, April fourteenth, eighteen hundred and seventy-nine, it appears that this company was incorporated by the court of common pleas of Venango county in April eighteen hundred and seventy-four. The company accepted the constitution and act of April twenty-ninth, eighteen hundred and seventy-four and its charter was approved by the Governor on April fourteenth, eighteen hundred and seventy-nine. There is no limit mentioned in the letters patent to the territory which this company is authorized to supply with water.

Works were constructed in eighteen hundred and seventy-seven. The original source of supply was the Allegheny River. Some years afterwards the supply was changed to various springs located on the mountain side in the borough but above the dwellings. Owing to the inadequacy of the spring supply it was abandoned. This was prior to the period of typhoid outbreak above mentioned.

The present works comprise a river intake, pumping station, distributing reservoir and the pipe system in the town.

The pumping station is located on the river bank at the foot of Eighth street immediately above the central portion of the borough. The water is taken from the river through an eight inch suction pipe, the outer end being in the centre of the river and having a free opening. It is about two hundred and fifty feet from the pumping station.

The pump house is a brick structure enclosing a pit of water tight masonry construction, eighteen feet in diameter and twenty-eight feet deep. In this pit is located the pumping machinery. There is an old horizontal steam pumping engine, now maintained for emergencies and a sixty horse power gas engine, belt connected to a triple Stillwell Bierce pump having a rated capacity of four hundred and thirty-two thousand gallons per day of twenty-four hours.

The water is raised vertically three hundred and eighty-feet through an eight inch and six inch line two thousand six hundred and ninety feet long to the distributing reservoir on the hill above the town. There is a six inch return supply main to the town, but the water may be pumped directly into the street mains by the manipulation of valves at the pump house. It is reported that the pumps are operated to fill the reservoir and that then they are shut down until the reservoir supply is depleted sufficiently to call for refilling of the basin.

This structure is stone masonry, open, circular, ninety feet in diameter on top and sixty-three feet in diameter on the bottom. When full to a depth of about ten feet, it holds three hundred and forty-six thousand gallons, or practically two days' supply for the town, the average daily draught being one hundred and eighty thousand gallons. The maximum is reported to be two hundred and fifteen thousand gallons and the minimum about one hundred and fifty thousand gallons per twenty-four hours. It is represented that a six inch drain pipe is provided to empty the reservoir for cleaning purposes. There is a six inch overflow at the top. There is no enclosure to prevent the malicious or accidental pollution of the water in the basin. The surface of the ground slopes away from the reservoir in all directions, so there is no possibility of any surface drainage contamination of the supply after it is introduced into the water works system.

The system of distributing mains in the streets totals a length of four and seven tenths miles. Over one mile is six inches in diameter, there are nearly two miles of four inch pipe, about one mile of three inch pipe and some two inch and one inch pipe. At convenient points in the village fire hydrants are installed. Along the river front there are several blow-offs which admit of the ready drainage of the water pipe system.

On the banks of the river a few hundred feet above the pump house is the woolen mill of Flinn Brothers, where wool is received in the fleece and manufactured into blankets. The peculiar wastes from this process are discharged directly into the river. Trade wastes from the Emlenton Refining Company's plant also go into the river above the water works intake.

The water company purposes to entirely abandon the river supply, if the new source be found adapted to its needs. Six wells have been drilled at the reservoir on the company's land. These wells vary in depth from two hundred and twenty-nine to three hundred and eleven feet. Each is cased off with six inch pipe to a depth of about one hundred feet from the surface of the ground where there is solid rock. It is purposed to place in each six inch pipe a three inch tube through which the water is to be raised into the reservoir with such appliances as are in customary use in the oil regions. The power is to be furnished by a gas engine.

The water bearing stratum into which the wells are drilled is a white sand rock, quite porous and having its general slope towards the Allegheny River. The location of this water bearing rock is about one hundred feet above said river. The springs in the borough along the side of the mountain are thought to be outlets of this same strata.

The country to the northward is rolling, generally cleared agricultural land, ascending gradually to the mountain summits several miles distant.

Eight hundred feet distant from the wells and on the hill is a cemetery of considerable area. Additions to it are contemplated. It is reported by those who are familiar with the local geological formation that below the top soil there is a hard rock difficult to drill and quite impervious to water. If this be true and the casing off of all surface waters has been effectually accomplished at the wells, there may be no danger whatsoever of any contamination of the remotest kind from the cemetery.

The petitioner prefers to secure a pure supply rather than to filter an impure water, and the proposed plans are offered for acceptance on this score.

The Allegheny River is known to be polluted by the sewage from the cities and towns along its banks. The city of Franklin is on the river twenty-eight miles above. The citizens of Emlenton fear the pollutions which are discharged into the stream at Franklin city and at other places. Tests of the raw river water, of the water in the reservoir and of the water taken from a tap in the town recently made by the Department revealed the presence of sewage organisms at these places. If this source is to be used, even for emergencies, the Emlenton Water Company should install a filter plant for the purification of the water. Such installation for temporary purposes or emergency uses would be as expensive as an installation for constant use. If the company is successful in its search for a new supply, then the Allegheny River should be entirely abandoned and the pumping machinery at the pump house should be disconnected with the river intake.

By trial only can it be demonstrated whether the driven well supply is a safe and abundant one. After the company shall have put its machinery in operation and have drawn water from the wells for a period of several weeks, a series of tests should be made to determine the quality of the water.

It has been determined that the proposed source of supply will not be prejudicial to public health and a permit is hereby issued therefor and for the extension of the water pipes in the streets, under the following conditions and stipulations:

FIRST. That before the proposed supply from the wells be used, the reservoir shall be emptied and thoroughly cleaned out and then shall be filled with water from the new source. A series of bacteriological tests of the well waters shall have been made prior to said filling of the reservoir and copies of these tests shall have been submitted to the Commissioner of Health.

On approval by the Commissioner of Health of the well water the reservoir shall be filled as above stipulated, and the water pipes in the streets shall be thoroughly flushed and cleaned out by the well water from the reservoir. If the supply be found insufficient in quantity, added wells shall be put down in order that all of the supply may be obtained from the ground.

SECOND. As soon as it shall have been demonstrated that the ground supply proposed is abundant in quantity and satisfactory in quality, the water company shall install adequate machinery, in duplicate if necessary, in order that the ground supply only shall be supplied to the public and then all connection between the river intake and the machinery in the pump house on the river bank shall be severed. If an adequate ground water supply be not found the water company shall thereupon install a water filter plant for the purification of the river water before it be supplied to the public and plans therefor shall be submitted to the Commissioner of Health for approval.

THIRD. Plans of the lands owned by the water company at the reservoir and showing the precise location of the wells shall be submitted to the Commissioner of Health. Also the results of the tests as to quantity of water yielded by these wells shall be submitted to said Commissioner. At the close of each season's work plans of water mains laid during the year shall be filed in the office of the State Department of Health, together with any other information in connection therewith that may be required in order that the Commissioner of Health may always be informed as to the extent of the water works and the number of people using the same.

FOURTH. If at any time in the opinion of the Commissioner of Health the water supply or the water works or any part thereof has become prejudicial to the public health, then the water company shall adopt such remedial measures as the Commissioner of Health may approve or suggest.

Since the existing supply is subject to pollution, the water company shall notify its consumers that absolute safety in the use of this water for domestic purposes can only be assured by the boiling of the water and shall advise its consumers to

boil the water for thirty minutes until such time as the Allegheny River supply shall have been discontinued or substituted by the proposed ground water supply.

FIFTH. The company shall keep a weekly report of the operation of the water works satisfactory to the Department of Health and submit copies thereof to the Commissioner of Health when required. If the company will notify the Department when it is ready to have tests made of the quality of the new supply, sample bottles will be sent for filling with proper directions how to collect the samples and how to ship them to the State Health Laboratories, and the Department will make the tests for quality. This is made optional with the company.

SIXTH. The water company shall provide an ample enclosure at the reservoir to obviate accidental or malicious contamination of the reservoir water.

The Department of Health will advise the local authorities to institute a careful examination and series of tests of the private well waters in the town for the purpose of ascertaining that wells or springs are contaminated and causing the abandonment of all such sources which are polluted.

Harrisburg, Pa., April 21, 1908.

VILLAGE OF ENOLA, EAST PENNSBORO TOWNSHIP, CUMBERLAND COUNTY.

Dauphin Consolidated Water Supply Company.

This application was made by the Dauphin Consolidated Water Supply Company and is for permission to extend its water works for the supply of water to the public in the village of Enola, East Pennsboro township, Cumberland county, Pennsylvania, and to obtain an additional source of supply therefor.

It appears that the Dauphin Consolidated Water Supply Company was formed by a merger and consolidation on May twenty-first, one thousand nine hundred and three, of three independent water companies, namely, the Citizens Water Company of Middle Paxton township, the Citizens Water Company of Dauphin borough and the Citizens Water Company of Susquehanna township, all of Dauphin county.

The said Citizens Water Company of Middle Paxton township was chartered in January, one thousand nine hundred and one, for the purpose of supplying water to the public in said township. The said Citizens Water Company of Dauphin borough was chartered on the same date for the purpose of supplying water to the public within the borough. The Citizens Water Company of Susquehanna township was also chartered on the same date and its district was limited to said township.

The new company has all the privileges and restrictions formerly obtaining with each of the three smaller companies.

Since said merger and consolidation, the Dauphin Consolidated Water Supply Company has purchased the franchise and property of two other water companies, one being the Progress Water Supply Company, chartered in nineteen hundred and five and authorized to supply storage or transportation of water and water power for commercial and manufacturing purposes in Susquehanna township, Dauphin county, and the other company being that of the Enola Water Company, chartered in nineteen hundred and three and authorized to supply water to the public in the township of East Pennsboro, Cumberland county.

The records in the office of the Secretary of the State show that said purchase and sale were made under provisions of the General Corporation Act of April twenty-ninth, eighteen hundred and seventy-four and the supplement of April seventeen, eighteen hundred and seventy-six, for it is so stated on the records. If a franchise be sold under the act of eighteen hundred and seventy-four, then, by the express provisions of said act, the vendor company ceases to exist. So it would appear for the purpose of this discussion that there is no longer such a corporation as the Enola Water Company and that the Dauphin Consolidated Water Company is the proper one to submit the application to the Commissioner of Health.

The former Enola Water Company's plant is independent of the other system of the water works owned by the Dauphin Consolidated Water Company. The source is ground water obtained from driven wells and pumped into a standpipe from which the village is supplied by gravity to the inhabitants of Enola village.

This village is of recent origin and comprises about two hundred dwellings erected for the accommodation of railroad men in the employ of the Pennsylvania Railroad. The classification freight yards of the Philadelphia Division of said railroad are in the village or between it and the west bank of the Susquehanna River opposite the northern part of the city of Harrisburg. The Realty Company which laid out the town built the streets and brought about the establishment of water works and sewerage systems does not have any control or say in the management of the water works system.

In the northern part of the town in a small ravine there are six driven wells between one hundred and two hundred feet deep from which water is pumped through a six inch main a distance of twelve hundred feet to a standpipe twenty feet in diameter and forty feet high and located on a hill the highest point in the village.

The driven wells are connected by a horizontal pipe to the small masonry covered basin which serves as the receiving gallery for the water from said driven wells. This water is ordinarily at an elevation of twenty feet or more below the surface of the ground, so it has to be raised and up to the present time the means employed has been compressed air. A horizontal duplex steam pumping engine of four hundred thousand gallons capacity is employed to lift the water from the collecting chamber into the sandpipe.

It is reported that the ordinary consumption of water in the town averages thirty-five thousand gallons daily. About seven hundred and fifty people are so supplied and the water is used exclusively for domestic purposes. There are times, however, during the summer months when the demand for supply of water is as great as the capacity of the driven wells. It is for the purpose of securing an auxiliary source and never failing supply which shall be available at any moment, that the petitioners ask approval of a plan to install an auxiliary pumping station and emergency intake to the Susquehanna River. In this connection it should be noted that the water works afford fire protection. There are fire hydrants conveniently located in the town.

The other district of the Dauphin Consolidated Water Supply Company's system is across the river from Enola and east and north of the city of Harrisburg. Here there are other villages and also an extensive freight yard or yards and shops of the Pennsylvania Railroad Company, all of which obtain their source of supply from the said water company. The supply is derived from Stony Creek a stream rising in the mountains north of Harrisburg and emptying into the Susquehanna River at the borough of Dauphin. A dam is built across this stream at an elevation sufficiently high to develop water power by means of which the supply is pumped to a masonry distributing reservoir holding about one hundred and seventy-five thousand gallons and located on the hill back of Dauphin borough. From here, the water is furnished by gravity to the district.

At the Enola yards water is supplied for locomotive and other purposes from a system of water works owned and maintained by the Railroad Company. There is an open earth reservoir on the hill near the water company's standpipe into which river water is pumped and stored for supply to the freight yards exclusively. The petitioners purpose to tap the pumping main leading from the river station to the open reservoir on the hill and to conduct the raw river water through a four inch pipe to a pressure filter to be located at the present pumping station of the water company.

One filter unit, a frame structure approximately six feet high and twelve feet square with a filtering area of approximately seventy square feet, is to be built. In the bottom of the filter there is to be a series of two and one-half inch brass strainer pipes, eighteen inches apart, which will serve as underdrains. A sand bed about thirty inches in depth is to be placed over the underdrain. The water will come on to the filter from a partition on the raw water inlet to the tank. High water level will be about eighteen inches above the top of the sand, and the top of the filter will be six inches above high water line. Alum will be fed in by gravity to the raw water just before it reaches the filter. No arrangement has been made for a re-wash valve to allow first filtered water to go to a sewer.

The filtered water will go to the main section well. There is to be no regulator to control the rate of filtration. A filter with an area of seventy square feet should take care of about two hundred thousand gallons per day of good coagulated water reasonably free from suspended matter but probably would have great trouble in satisfactorily purifying muddy river water. It is evident that unless some improvements be made to the design that the filter will be unable to purify river water, even if clear and then not at a rate in excess of one hundred million gallons per acre, or approximately one hundred and fifty thousand gallons per day for the filter unit proposed.

In so far as the Department is now informed, it appears that with a full standpipe and with the proposed filter the water works system would be capable of furnishing two good fire streams during adverse conditions, provided the river water were clear and only satisfactorily filtered water were admitted to the system. The danger to public health, where there is an installation between a polluted source of supply and the water consumer, of apparatus designed to purify the water lies in the possibility that in an emergency, the necessities of the case may be considered great enough to warrant the discarding temporarily of the safe guard and the admittance to the water works system of unpurified river water.

This danger should be minimized to a reasonable degree which in this instance suggests the installation of a second filter unit coupled with a sedimentation basin having a capacity of at least two hours' supply in which thorough coagulation of the raw river water should be accomplished.

Furthermore rate controllers should be provided to obviate any excessive rate of filtration.

Because the filtered water is to be discharged at once into the pump well, some attention should be paid to a modification of the plans whereby the first filtered water after cleaning may be wasted to the sewer.

The fact is not overlooked that the proposed improvements are in anticipation of shortage of water which shortage has not actually been experienced. So the use will be occasionally which renders all the more important that the plant be equipped with appliances to insure a proper purification of the river water.

The washing of the filter is to be accomplished by pressure from the supply main. The overflow weir for dirty water is twelve inches only above the sand surface which is too little to admit of proper washing. Much sand is bound to be wasted. It would be well to provide a gravel underdrain. The design as now submitted does not warrant approval if it be the intention of the petitioners to use the filter during muddy stages of the river, because in all probability the plant would be totally unable to handle this kind of water without a sedimentation tank.

It is understood that the proposed auxiliary supply is a temporary expedient only, and that finally an adequate and permanent supply is to be obtained from some source not now determined upon. This is urged as a reason why the filter plans on the small scale have been offered for approval. The water company wishes to avoid any unnecessary expenditure at this time. It is probable that a two hydrant stream service of six hours' duration will meet the immediate demands of the village and that the extreme conditions above mentioned will not obtain. It would be much better and safer if the water company would add a filter unit but this may be left for the future. However, since it is necessary in the opinion of the water company to install the filter, it is necessary that the apparatus accomplish in fact what its existence at the pumping station will warrant the water consumers in believing is being accomplished, namely, the purification of the water. Therefore, a sedimentation tank should be installed in conjunction with the filter, the plant provided with the equipments above mentioned in connection with regulation of rate of operation and cleaning, appliances which are inexpensive and yet important. Observations throughout the season of nineteen hundred and eight should then demonstrate whether the adding of a filter unit to the plant is necessary.

It has been determined that the proposed additional supply will not be prejudicial to public health, and a permit is hereby and herein granted therefor provided it be within the charter right of said water company to obtain its source of supply temporarily from the Pennsylvania Railroad Company's system of water works. This permit is granted under the express stipulation that if the Dauphin Consolidated Water Supply Company does not have the right to obtain this source of supply from the Pennsylvania Railroad Company's system of water works, then said water supply company shall first acquire the intake pumping station and rising main or whatever apparatus may be necessary to introduce the river water to the proposed filter. And this permit is issued under the further conditions and stipulations as follows:

FIRST. That plans of the water purification plant as built shall be filed in the office of the Commissioner of Health together with any other information in connection therewith that may be required and that at the close of each year's work a plan of the entire water works system of the said water company showing all additions to the street mains laid during the year shall be prepared and filed in said Commissioner's office to the end that there shall always be a complete map of the existing water works in said Commissioner's office.

SECOND. The water company shall provide sedimentation of the coagulated water and shall use a coagulant whenever the filter be operated. The modern equipments hereinbefore mentioned shall also be provided for the filter and a record of the operation thereof shall be kept on forms satisfactory to the Department of Health whenever required.

THIRD. If at any time in the opinion of the Commissioner of Health the water supply has become prejudicial to public health, then the water company shall adopt such remedial measures as the Commissioner of Health may approve or suggest.

FOURTH. Regular inspections will be made of the system by a Department officer and the State Department of Health may suggest rules and regulations to govern the supplying of water to the public in so far as the public health is concerned. The water company shall co-operate with the Department, furnish facilities for inspection and assist in the examination if this be required.

Harrisburg, Pa., April 2, 1908.

FAIRCHANCE BOROUGH, FAYETTE COUNTY.

This application was made by the borough of Fairchance, Fayette county, Pennsylvania, and is for permission to establish a system of water works, in the town and to obtain a source of supply from the Trotter Water Company, under the following conditions and stipulations:

It appears that Fairchance borough is a manufacturing community of about twenty-one hundred population, located in the southwestern part of Fayette county on the western slopes of Chestnut ridge, a mountain whose summits are fifteen hundred feet or more above the borough. This ridge is about three miles east of the borough and it extends through the county from the Monongahela River on the southwest to the Youghiougheny River on the northeast. Connellsville borough is on the latter at the foot of the west slope of the mountain, and Uniontown borough is also west of the mountain between Fairchance and Connellsville. The main line of the Baltimore and Ohio Railroad passes northerly along this mountain slope throughout the borough of Fairchance, Uniontown and Connellsville. A branch of the Pennsylvania Railroad system from Greensburg extending southerly and passing through Uniontown terminates at Fairchance. There is also an electric railroad line leading from Fairchance northward to Uniontown and Connellsville.

Fairchance borough is at the headwaters of Georges Creek about seven miles north of the State line between Pennsylvania and West Virginia. Georges Creek rises in several mountain runs immediately west of the borough, these runs coming down in parallel lines through deep ravines and forming the main creek in the borough. A tributary, Muddy Run, rises north of the borough, perhaps three miles distant, and on it there are several coal mines and coke operations. This stream follows closely the western boundary of Fairchance and joins Georges Creek a few hundred feet below the southwestern corner of the town. Thence Georges Creek flows in a general southwestern direction to the Monongahela River, nine miles distant. The borough of New Geneva is on the river at the mouth of the creek. The distance traversed by the stream is an unpopulated, mountainous, wild region.

The principal industry which supports the inhabitants of Fairchance borough is the mining of coal. However, the coke interests are large. The Frick Coke Company operates the Kyle Mine, which is located partly in the western section of the borough and partly in George township, which surrounds the borough. This plant is in Muddy Run Valley. The company employ about three hundred people and use water supplied by the Trotter Water Company. In the borough there is also the Kanawha Glass Company, makers of window glass. This concern employs about two hundred and twenty-five hands. The United Fire Brick Company, located adjacent to the glass plant, employs about thirty hands. There are no public sewers in the community, but there are three private sewer lines discharging into Muddy Run and two private sewers discharging into Georges Creek. The largest part of the built up section of the borough drains into the creek. This stream is clear, pure, mountain water, but Muddy Run is aptly named. It receives large quantities of mine drainage and the color of its waters is characteristic of sulphur pollution. The acidity of the run renders the stream unsuitable for domestic and industrial uses. There are coal mines which drain into Georges Creek below Fairchance borough so that this natural water course is practically preempted for mine drainage purposes.

At the present time the people of Fairchance borough derive their drinking water from dug wells and a few drilled wells. These are usually sunk to a depth of about twenty feet below the surface of the ground. Some of these sources are polluted by surface drainage from street gutters. As they are in proximity, in many instances, to loose earth privy vaults and cesspools there is reason to believe that contamination of the drinking waters result from this proximity and the disposal of sewage into loose privy vaults and cesspools. The discharge of sink water and wash water on to the ground in street gutters is also a menace. Typhoid fever has been prevalent in the borough. During nineteen hundred and seven, two physicians treated at least sixty cases. They were not reported to the State Department of Health. The towns people realize that there should be better methods of sewage disposal, and there is an application at this time pending before the Commissioner of Health relative to the building of a public sewer line in Church street, the main thoroughfare of the village.

The headwaters of Georges Creek are about three miles distant east of Fairchance in a wooded, mountainous territory which is uninhabited. If this drainage area were secured by the borough and maintained in its present condition, it could be developed to supply an abundance of water of excellent quality. Owing, however, to the cost of constructing adequate impounding reservoirs on the mountain slopes and the fact that the streams, during dry weather, practically run dry, it has been determined that it would not be practical for the borough to undertake to seek water supply from these sources. The borrowing capacity of the borough of Fairchance is insufficient to defray the cost of such a municipal improvement. However, the local authorities have decided that the public health demands that there shall be a public supply of pure water and purpose to bring this about. The plan is to purchase the water from the Trotter Water Company, the borough to lay the mains in the streets only. The municipal authorities have entered into a contract with the Trotter Water Company to furnish water to the borough for a period of ten years, from May, nineteen hundred and eight, the supply to be two hundred thousand gallons per day, and the contract to be cancelled by either party on sixty days written notice. The contract also provides a renewal privilege at the end of the ten year term. The borough has, in consequence of this contract, made application for permission to lay the water mains in the various streets of the borough and to connect them with the Trotter Water Company's eight inch main at the coke ovens.

The borough has also executed a contract for the construction of the water mains in the streets and the contractor is engaged at the present time in building the system.

The Trotter Water Company was incorporated under the act of eighteen hundred and seventy-four. The charter was granted on October twenty-ninth, eighteen hundred and eighty-eight, the place of business being Scottdale. The object of the company was the supplying of water to the public in Dunbar township, Fayette county. The notice of the merger and consolidation of the Trotter Water Company, the Youghiogahela Water Company and the Youghiogheny Water Company under the name of the Trotter Water Company was filed in the office of the Secretary of the Commonwealth on August twenty-eighth, nineteen hundred and five.

Youghgahela Water Company was formed by the merger and consolidation for four water companies, the papers being filed July eleventh, nineteen hundred and five. These four companies were given the name of the Youghgahela Water Company. They were the Lemont, Huron, Redstone and Fairchance Water Companies.

The Lemont Water Company was chartered February sixteenth, nineteen hundred and four for the supplying of water to the public in the township of North Union, Fayette county surrounding Uniontown borough.

The Huron Water Company was chartered February sixteenth, eighteen hundred and ninety-nine for the supplying, storage and transportation of water and water power for commercial and manufacturing purposes in the township of German, Fayette county. This township extends easterly from the Monongahela river.

The Redstone Water Company was chartered October seventeenth, eighteen hundred and eighty-seven for the supplying of water to the public in the township of South Union, Fayette county. This township lies south of Uniontown borough and south of North Uniontown township. In it are the villages of Hutchinson and Brownfield.

The Fairchance Water Company was chartered October twenty-seventh, eighteen hundred and eighty-seven for the purpose of supplying water to the public in George township, Fayette county. Fairchance borough is in this township. This township lies between South Union and German townships.

So the four said water companies form a tier of townships which, with the original Trotter Water Company territory, extends from the Youghiogheny River along the western slope of Chestnut Ridge to the Monongahela River.

The Youghiogheny Water Company was chartered on October twenty-seventh, eighteen hundred and eighty-one for the storing and transportating of water for the public use from the Youghiogheny River at or near Broadford, Fayette county through Lynn and Connellsville townships in Fayette county to a point at or near Mount Pleasant. The place of business of the company was Scottdale. Mount Pleasant and Scottdale are in Westmoreland county.

Thus the present Trotter Water Company has a large charter territory along the western slope of Chestnut Ridge from Mount Pleasant in Westmoreland county, to the Monongahela River, a total distance of thirty miles.

The Trotter Water Company, at the present time, has two main sources of supply, namely, the Youghiogheny River and the Monongahela River.

The main pumping station is located in Dunbar township on the west bank of the Youghiogheny River at a point opposite South Connellsville. Connellsville borough is below. The river is reasonably free from sewage and mine drainage pollution above Connellsville. It is known that tanneries and lumber camps and small settlements abound on the banks of the streams. As far as the Department is aware, the borough of Somerset in Somerset county is the only municipality within Pennsylvania having a sewer system from which sewage is discharged into the river or a tributary. This borough's sewage goes into Coxes Creek, which in turn flows into Casselman River. The point of discharge of sewage is fifty miles above Connellsville.

The Yougiogheny River rises in West Virginia. Above Connellsville the drainage area is at least one thousand square miles. It is generally wooded, rugged, mountainous territory. The principal tributary is the Casselman River. This stream and Laurel Creek and the Upper Youghiogheny River unite and form the main stream at Confluence borough. Casselman River receives the drainage of quite a number of coal mines and it appears that the sulphur waters are largely diluted before Connellsville is reached. At and below this point, sewage, mine drainage and industrial refuse is discharged into the stream all along its course. The Trotter Pumping station is about one and five-tenths miles above Connellsville borough. The water is taken from the river through an intake tunnel five feet wide and eight feet deep leading to a pump well fifteen feet by forty feet in plan and twenty-five feet deep. A wire screen of three-eighths inch mesh is placed at the entrance of the tunnel. There are two sixteen inch suction pipes inserted into the well. They connect to two duplex, horizontal pumps installed in the station, each pump having a capacity of five million gallons per twenty-four hours. There are also two Wilson-Snyder pumps at the plant. The water is raised through a twenty-four inch force main to a reservoir of three and one-half million gallons capacity, located on top of the mountain, distant one-quarter of a mile back from the pump house. This reservoir is excavated out of rock and is built of cement masonry. It is elevated four hundred and forty-two feet above the pumping station. There is an overflow pipe from it sixteen inches in diameter and a twelve inch drain pipe. From this reservoir a twenty-four inch gravity main is laid southwesterly through Dunbar and North Union townships, passing through the villages of Pechin, Mount Braddock, Youngstown and Lemont Furnace to coke ovens about two and one-half miles east of Youngstown borough where the storage reservoir of seventeen million gallons capacity is located. This point is seven miles distant from the Dunbar reservoir. The Uniontown reservoir is on an eminence and higher than the surrounding country. From this reservoir, continuing in a southwesterly direction one mile, there is a twenty inch water main reducing to a sixteen inch main which continues in the same general direction for a distance of four and one-half miles, passing Leith village where a six inch line branches off supplying this settlement in South Union township. A short distance beyond the Leith branch is an eight inch

branch extending northerly to a protected reservoir known as Continental Number One, having a capacity of five hundred thousand gallons. This is situated on high ground above Uniontown about one-half mile west therefrom. Beyond Leith, off of the sixteen inch there is a six inch branch southerly leading to the ten million gallon reservoir on the highland above Brownfield village in South Union township. This reservoir supplies the Brownfield coke ovens. Thence continuing southwesterly, the sixteen inch main reduces to a fourteen inch, at this point there being a six inch branch southerly which supplies Oliphant Furnace, which is one and one-half miles beyond Brownfield. About one mile further southwest off of the fourteen inch main is a four inch branch leading to coke ovens about three-quarters of a mile west of Oliphant Furnace. One-half mile beyond this branch the fourteen inch main terminates in a twelve inch and an eight inch. The eight inch extends southerly to the coke ovens of the Frick Coke Company at Fairchance borough to a reservoir having a capacity of one and one-half million gallons. The twelve inch pipe continues southwesterly to a ten million gallon reservoir in George township about two miles northwest of Fairchance borough. This reservoir is formed by a dam constructed across the valley of Yorks Run. There is a pumping station located near this reservoir which is used to increase the pressure to the consumers. This force main is twelve inches in diameter and extends westerly to the small village of Shoaf on the Smithfield and Masontown Branch of the Baltimore and Ohio Railroad. There is a six inch branch off the twelve inch pipe to the village of York Run. From the seventeen million gallon reservoir called Uniontown reservoir, which is near Cool Spring village and the Cool Spring coke ovens, there is an eight inch branch extending northwesterly for a distance of about four miles, passing through the village of Oliver to Phillips in North Union township. The line of this water main passes about one mile northeast of Uniontown and terminates at a point two miles north of the borough.

From the said Continental reservoir number one, an eight inch line extends southwesterly a distance of two miles to a protected reservoir of five hundred thousand gallons capacity known as Continental number two.

Three-quarters of a mile south of this reservoir is another reservoir, capacity nine million gallons. One-half mile west of it there are two reservoirs having a combined capacity of twenty-one million gallons. These three basins are impounding reservoirs at the headwaters of small runs. From Continental number two, a six inch main extends westerly to Continental reservoir number three. Detail plans of the reservoirs have not been filed in the Department, and so the capacity of number three is not known. Between the last two reservoirs is Thro Mine, which is supplied by the said six inch pipe. From Continental number three there is an eight inch pipe line extending westerly down the valley of the North Branch of Browns Run, a distance of about four miles to Leckrone village at the junction of the north and south forks of Brown's Run. This point is about two and one-half miles easterly of the mouth of the run at the Monongahela River.

The Trotter Water Company's Huron pumping station is located in German township on the east bank of the Monongahela River at the mouth of Brown's Run. Information about the pumping capacity and details of the intake are not in the possession of the Department. The raw river water is raised through a twenty-four inch force main to a standpipe about one mile distant from which there is an eighteen inch main reducing to ten inches and finally eight inches in diameter, which supplies the villages of New Salem and Buffington in German township. Eight inch branches reach the villages of Lambert and Edenborn in the same township. Off this main line there is a twelve inch branch to McClellandtown and thence southerly the pipe is ten inches in diameter connecting to the eight inch main at the village of Leckrone. The latter pipe as hereinbefore described comes from Continental reservoir number three. Thus the raw Monongahela River water may be forced into the pipe system leading to the Trotter pumping station on the Youghiogheny River. The Monongahela River water is polluted with sewage and mine drainage also by refuse matter from steamboats which pass by the intake. The supply is unsuitable for drinking purposes without purification. Ordinarily, Youghiogheny water is supplied to Fairchance coke ovens and to Continental reservoir number one. It is understood that it is seldom if ever that the Monongahela River water is forced into the water mains beyond Continental number one. It is used principally for the coal mines and coke ovens in the southwestern part of Fayette county.

The Connellsville Water Company which furnishes drinking water to the borough of Connellsville takes its supply from the Youghiogheny River more than a mile upstream above the Trotter Water Company. However, the Connellsville Water Company filter the supply before furnishing it to its consumers. The Trotter Water Company, however, supplies its consumers with raw Youghiogheny River water.

The Trotter Water Company has a third pumping station. It is located at Broadford on the north bank of the Youghiogheny River about one and one-half miles below Connellsville borough. The stream here is subject to great pollution from mine drainage, industrial wastes and the sewage of the boroughs of Connellsville and New Haven and is totally unfit, without purification, to be used as a source of drinking water. The Department does not have a plan of the pumping station and intake or information as to the capacity of the outfit. It is understood, however, that the Broadford pumps are used only in a case of an emergency. From this point a force main twelve inches in diameter extends up Jacob's Creek, a distance of about two and one-quarter miles to Summit Heights, where is located a reservoir

having a capacity of eleven million gallons. From this point a gravity main twelve inches in diameter extends about one and one-half miles northerly to Scottdale borough. There are coke ovens here which are supplied by the Trotter Water Company. There is a six inch pipe under the river to the south side connecting with the pipe system which receives its supply from the Dunbar reservoir, so it is reported. The main from the Dunbar reservoir is eight inches in diameter and extends northerly for about two miles and branches into two twelve inch pipes. One twelve inch pipe extends southwesterly supplying the village of Leisenring and the Monarch coke ovens, whence the pipe reduces to eight inches in diameter and extends southwesterly to the village of Bute and West Leisenring. This point is six miles from the eighteen inch pipe. From the Monarch coke ovens there is a ten inch pipe reducing to an eight inch line which extends northerly one and one-half miles to Juniataville about one mile north.

The other twelve inch branch extends northerly about one mile to New Haven borough with an eight inch branch at Trotter village extending northerly to Adelaide village on the south bank of the Youghiougheny River, and off from this eight inch pipe is a six inch line above mentioned as passing along the river to the Broadford station. A submain four inches in diameter off from the six inch pipe extends under the river to Davidson mine adjacent to Connellsville borough.

Thus it is seen that the Trotter Water Company has three different pumping stations connected by a system of water mains so that it is possible that any one of the stations can furnish water to the entire system.

The blueprint submitted by Fairchance borough of its proposed water works shows that the local authorities purpose to lay one and fifteen one-hundredths miles of eight inch pipe, one and nine one-hundredths miles of six inch pipe, and one and nineteen one-hundredths miles of four inch pipe. Fire protection is to be afforded as well as drinking water. The citizens believe that the quality of the water to be furnished by the Trotter Water Company is preferable to that of the polluted wells in use in the borough.

The feed main is to be eight inches in diameter and is to be laid a distance of twenty-nine hundred feet to a standpipe in George township belonging to the Trotter Water Company and already described. The water is to be purchased by meter rate.

It is purposed to secure flushing of the water mains in the streets through fire hydrants, some of the hydrants to be located at low points in the borough. It is not expected that the citizens will very generally use the supply for drinking purposes at the beginning, but that ultimately the majority of them will be consumers.

It is reported that the borough intends to use the Trotter Water Company's supply until such time as the finances of the municipality will permit the development of the Georges Creek source.

At present, there is no Board of Health in Fairchance borough, and consequently sanitary rules and regulations are not enforced. The interests of the public health demand the introduction of a pure water supply and also the protection of the existing well waters. An application for public sewerage is now pending before the Commissioner of Health, but the plan submitted does not comprise a complete sewerage system. Attention should be paid to the present method of sewage disposal into cesspools and privy vaults in proximity to wells. The citizens should be informed that the drawing of water from the ground near privies and cesspools is dangerous and that so long as the present method of sewage disposal prevails, the borough is threatened with a widespread epidemic of a water borne disease. Garbage disposal is a menace and improved methods should receive the attention of the local authorities.

Probably the Youghiogheny River water will be less prejudicial to public health than the present domestic wells in Fairchance borough and hence the introduction of this water in the town should be a benefit to the community. However, the Monongahela River is totally unsuited to be used as a source of public supply in Fairchance borough. Even the Youghiogheny River is subject to accidental pollution and the water should be filtered.

It has been determined that the proposed water works system and source of supply will not be prejudicial to public health under certain conditions and a permit is hereby and herein granted under the following conditions and stipulations:

FIRST. Before the proposed source of supply is introduced into the borough of Fairchance the borough shall prepare plans for the installation of a water filter plant for the purification of the water supplied and shall submit said plans to the Commissioner of Health for approval and after the plans are modified, amended or approved the borough shall erect a filter plant and put the same in operation and maintain a filter therefor so long as the Trotter Water Company's source of supply be used by the borough. The cost of such water filter installation need not be expensive and as a safeguard, should provide the cheapest kind of insurance to public health health in the borough.

SECOND. The borough shall provide adequate drainage facilities for the speedy drainage of the water works system and shall show location on a plan and submit a written description of such facility. At the close of each season's work the borough shall submit a plan of the water pipes laid during the year together with any other information in connection therewith that the Commissioner of Health may require in order that the Department shall always be informed of the full extent of the water works system and the public use thereof.

The local authorities' attention is especially called to the suggestions hereinbefore offered relative to the changes in the existing methods of sewage and garbage dispesal. The borough council should notify the citizens to boil the water taken from domestic wells and springs of the borough and used for domestic purposes.

A local board of health should be established forthwith and sanitary rules and regulations should be promulgated and enforced in the interests of the public welfare.

Harrisburg, Pa., October 5, 1908.

FREEPORT, ARMSTRONG COUNTY.

Freeport Water Works Company.

This application was made by the Freeport Water Works Company of the borough of Freeport, Armstrong county, Pennsylvania, and is for approval of plans for the installation of a mechanical filtration plant for the purification of the water to be supplied, and for the extension of water pipes in the streets of the borough.

The borough of Freeport is located in Armstrong county, Western Pennsylvania, on the Allegheny River thirty miles northeast of Pittsburg. It is in the extreme southwestern corner of Armstrong county, where said county abuts Westmoreland, Allegheny and Butler counties. The borough is bounded on the north by South Buffalo township in Armstrong county, on the east by said township and the Allegheny River; on the south by the Allegheny River which separates it from Westmoreland county; and on the west by Buffalo Creek which lies a few hundred feet east of the Butler county line.

One mile above the borough the Kiskiminetas River joins the Allegheny. Buffalo Creek, which enters the Allegheny River at the western edge of the borough, is a small tributary which drains approximately one hundred and fifty square miles of territory in Armstrong and Butler counties.

The incorporated area of the borough, consisting of two hundred and fifty acres, is located on land which rises gradually from the Allegheny River and Buffalo Creek to a ridge located parallel to the river and approximately a half mile therefrom. The land immediately along the bank of the river and Buffalo Creek is about fifteen feet above the normal stage of the river and is subject to floods during high water. The land at the extreme northeastern edge of the borough at the summit of the ridge is two hundred feet higher.

Freeport is mainly a railroad center. Across Buffalo Creek on the western boundary of the borough is Butler Junction, a terminal of the Butler Branch of the West Penn Railroad. One mile east of Freeport, across the Allegheny River, is Kiskiminetas Junction, where the Allegheny Valley Railroad joins the West Penn Division. The West Penn Division of the Pennsylvania Railroad passes through the center of the borough, furnishing easy access from Butler Junction and Kiskiminetas Junction. Most of the railroad employes at these two places live in Freeport, comprising about thirty per cent. of the total population.

The present population within the incorporated limits of the borough is estimated to be two thousand. The borough is one of the oldest in the western part of the State of Pennsylvania and the growth has been slow. The population in eighteen hundred and eighty was fifteen hundred and in nineteen hundred was seventeen hundred and eighty, so it is probable that the population twenty years from now will not be more than twenty-five hundred. In addition to the population within the borough limits, there is a settlement at Butler Junction and also a suburban district in South Buffalo township immediately east of the borough limits which are supplied with water by the water works company. With these additions, it is estimated that the total population within the territory of the water works company is twenty-five hundred, with a probable future population of three thousand.

In addition to being a railroad center, Freeport has one large industry, the Guckenheimer Distillery, located on what was formerly known as Todd's Island on the Allegheny River at the southeast end of the borough. This island was purchased by the distillery company and a part of the narrow eddy separating it from the mainland has been filled in. The island, which is two thousand feet long and five hundred feet wide, has been laid out in lots and streets and the houses of the employes are located thereon, in addition to the distillery ware houses and buildings. The distillery employs one hundred and sixty-five men. It is supplied with a private water supply for domestic purposes, but uses the water from the Freeport Water Works Company for fire purposes. The private supply consists of the raw river water for the boilers and a driven well supply for the distillery. A pumping station is located on the bank of the river, equipped with two vertical triplex pumps, each with a capacity of two hundred and fifty gallons per minute and both directly connected to a gas engine. One pump draws the water directly from a crib located in the bottom of the river about twenty feet from shore and pumps this water through a five inch wrought-iron main to the boiler house. The second pump is connected with five wells driven along the bank of the river to a depth of forty feet and lined with six inch casing. This water appears to be in good condition and is forced through a five inch wrought iron main to the distillery.

West of the borough at Butler Junction across Buffalo Creek, there is another distillery known as the Montrose Distillery, belonging to the Pennsylvania Distilling Company. This distillery is supplied with water by the water company.

At Butler Junction are located the watering tanks for supplying the engines and round house on this division of the railroad. The railroad company has no independent supply, but is furnished with water by the water company.

The borough is equipped with a combined system of sewers which drain half the area of the borough. These sewers range in size from twenty inches to eight inches and discharge into the Allegheny River and Buffalo Creek through five independent outlets. Sewers were first installed in eighteen hundred and ninety-six, when the Singer Sewer Company constructed three thousand feet of sewer in the central portion of the borough. The system has been developed more recently to its present size and the borough officials are planning extensions in the immediate future which will drain the remaining built-up section of the borough not sewered at present. It is estimated that thirteen hundred people are using sewers at present with a total of two hundred and fifty connections to sewers. The remaining population use dry earth vault privies, of which there are over three hundred in the borough.

In addition to the public sewer system, there are many private sewers emptying directly into the river from the houses located along the river front. The distilleries also have independent sewerage systems which discharge directly into the river.

The Freeport Water Works Company was incorporated on June twelfth, eighteen hundred and eighty-three, for the purpose of supplying water to the public and persons and corporations in and adjacent to Freeport borough, Armstrong county, Pennsylvania. It is generally held that the charter territory of a water company must be confined within definite limits, and if this should apply to the Freeport Water Works Company's charter, it would limit the company strictly to the borough of Freeport. However, the company has presumably the belief of charter security to supply the public in territory adjacent to Freeport borough, namely, Butler Junction and properties in South Buffalo township. It might be better for the company to make an application for and secure an extension of its territorial rights to these places. Such a course would effectually settle any question of authority.

The company supplies five hundred thousand gallons of water per day, of which three hundred thousand gallons are used for industrial purposes. The railroad company at Freeport Junction is the largest consumer.

Practically every house in the borough is connected to the water mains and in addition the settlement at Freeport Junction and also that in South Buffalo township immediately east of the borough are generally supplied by the company.

The water furnished by the company is, however, not used generally for drinking purposes. There is a prejudice against the use of this water due to its being taken directly from the Allegheny River, which is highly polluted, and also to the muddy condition of the water during the flood stages of the river. The people in the borough use several springs which outcrop at various points in the borough between the ridge and the river, and probably a dozen dug wells. These wells range from four to six feet in diameter and go to a depth of thirty feet where the bottom is about on a level with the river bed. The wells are lined with dry rubble field stone.

The existing water works system consists of a pumping station located on the Allegheny River about three-quarters of a mile above the borough proper and one thousand feet from the borough line, in South Buffalo township; three storage tanks with a total capacity of two hundred and fifty thousand gallons located on the ridge at the eastern edge of the borough immediately on the borough line; and six miles of supply mains ranging in size from three inches to ten inches.

When the water works were first constructed in eighteen hundred and eighty-three, water was taken from the river at a pump station located on the main land near the eastern end of Todds Island. In eighteen hundred and ninety-two this pump house was abandoned and the existing pump house was constructed.

Water is taken from the Allegheny river at this pumping station through two wooden cribs located six feet below the river bed and covered with sand and gravel. These cribs are located fifty and one hundred and fifty feet from the river bank, respectively. The crib nearer the bank of the river is fifteen feet by thirty feet by five feet deep and is connected with the pumps by a twelve inch suction line of flanged pipe. The other crib is sixty-five feet by fifteen feet by four and a half feet deep and is connected by an eight inch wrought iron pipe line. During low water periods the crib nearer the bank is out of service.

The pumps are located in a circular pit twenty-one-feet in diameter and twenty-eight feet deep, with the floor line ten feet above low water mark. The top of the pit is several feet above the highest flood. The walls of the pit are constructed of brick laid in cement and are two feet four inches thick. The bottom consists of a nine foot thickness of concrete. In the bottom of the pit are located the two pumps, consisting of a Gould single-acting vertical triplex pump of one million gallons capacity and a Wilson Snyder horizontal duplex steam pump of one-half million gallons capacity. The plunger rods of the Gould pump are carried vertically up to the shafting located above the top of the pump pit and directly connected to an eighty horse power gas engine. The top of the pump pit is covered by a brick pump house twenty feet by forty feet interior dimensions, which also covers the engine room in which the gas engine is located. Adjacent to this pump house is a brick structure

fifteen feet by thirty feet interior dimensions, containing one steam boiler of fifty horse power capacity This boiler develops steam at eighty pounds pressure which is used for driving the steam pump.

Forty feet northeast of the pumping station there is a piggery and slaughter house belonging to Philip Steislinger, butcher, located on top of the bank of the river and draining directly therein. The run-off from this piggery is a menace to the water supply of the borough.

The discharge line from the pumping station consists of a ten inch cast-iron force main extending west from the station along the main public road for a distance of twelve hundred feet to a point at the foot of the slope immediately below the storage tanks. At this point there are two pipe lines, five hundred feet long each, extending at right angles to the road up the hill to the tanks, six inches and ten inches in diameter, respectively. Water can be pumped through either of these lines to the storage tanks, or it can be pumped directly into the town mains through a six inch line extending from this junction point along the public road into the built-up section of the borough. The usual method of operation is to pump through the ten inch line to the storage reservoirs and to use the six inch line to supply the six inch mains leading from this junction point to the town.

There are eight houses located between this junction point and the pump house. These houses are supplied directly from the force main with raw water. The officials of the water company, however, state that it is their intention during the coming year to lay a supply main from the present distributing system to these houses so that they can be supplied with filtered water.

The storage reservoirs are located two hundred and twenty-five feet above the floor in the pump house pit and sufficiently high to furnish a pressure of eighty-five pounds on the hydrants in the main sections of the borough. The tanks are near the top of the ridge at the eastern edge of the borough and the borough line passes through the location. North of the tanks the land rises thirty-six feet higher where the crest of the hill is reached. The tanks consists of wood stave structures banded horizontally with circular steel bands and with a total capacity of two hundred and fifty thousand gallons. The two larger tanks are thirty feet each in diameter and twenty feet high. The smaller tank is twenty-four feet in diameter and sixteen feet high. These tanks are directly connected at present, so that the flow line in the larger tanks is governed by the depth in the smaller tank which is fifteen feet.

The ten inch force main enters the two larger tanks through ten inch connections located at the top of the tanks. At a point one foot above the bottom of the tanks there are six inch valved connections to the six inch supply main. The smaller tank connected at the bottom with the six inch line from the force main at the foot of the hill.

The borough is supplied from the tanks through this six inch main which is now used as a supply line and also through a six inch main extending from the tanks along High street and through a four inch main extending along Franklin street. These supply mains are so arranged with valving that one or more can be placed out of commission without cutting off the supply to the town.

The two six inch mains extend through the entire length of the borough along Market street and High street and are four hundred feet apart. The other streets are supplied with four inch and three inch lines. A four inch extension from the six inch main on Market street supplies the Butler Junction district. The pipe system is well equipped with valves. The dead ends are supplied with blow-off connections discharging directly into the river, or with hydrant connections. Fire hydrants are located at street corners at distances ranging from four hundred to eight hundred feet. Many of these hydrants are connected with three inch and four inch supply lines.

There has always been considerable typhoid fever in the borough of Freeport. The statistics of the number of the cases and deaths are not complete. The records of the cases are unreliable. The records of the State Department of Health are very incomplete relative to typhoid fever cases, showing that the physicians are lax in submitting reports. For the last ten years from three to twenty-two deaths per annum are reported. The twenty-two deaths occurred in nineteen hundred and seven. For that year only twenty-seven cases were reported. There is more likelihood that two hundred and seventy cases of typhoid occurred during that year.

The epidemic in the fall of nineteen hundred and five, when sixteen cases occurred in two weeks was attributed to a polluted milk supply, as all those stricken with the disease were supplied by one milk dealer at whose farm there was a case of typhoid fever, so it is reported.

The proposed filtration plant is to be located immediately above the existing storage tanks near the crest of the hill. It is proposed to install these filters in two units each with a capacity of five hundred thousand gallons and also to construct on top of the crest a settling tank having a capacity of one hundred thousand gallons. A coagulant pump and chemical mixing apparatus are to be located at the existing pumping station for introducing a coagulant into the force main.

The coagulant plant will supply sulphate of alumina to the water in definite proportions. Two cedar tanks, each three feet in diameter, and three feet deep, will be used for dissolving the coagulant. The alum will be placed in a small dissolving box located at one side of each tank and will be slowly dissolved by allowing a stream of water to trickle over it. One tank will be in commission while the solution is being dissolved in the other. A bronze pump, bolted to the side of the high pressure

pump and directly connected there to, will force the solution into the discharge compartment of the pump. This bronze pump is so arranged that the length of the stroke can be increased or diminished in proportion to the amount of coagulant desired and the rate of pumpage is in proportion to the rate of the main pump.

The water will be delivered through the existing ten inch main to a settling tank located on the crest of the hill. It is proposed to leave the existing connections from this ten inch main to the two storage tanks and also to the six inch supply main at the foot of the hill in position, so that they can be used to by-pass the water around the filters, or around both filters and storage reservoir in case of emergency.

The settling tank will consist of a circular white cedar structure, covered with a wooden roof, thirty feet inside diameter and nineteen feet deep. The bottom of the tank will be thirty-six feet above the top and one hundred and fifty feet north of the existing storage reservoirs and will rest upon concrete foundations, twelve inches wide, five feet ten inches center to center and extending the full width of the tank. The capacity of the tank, one hundred thousand gallons, allows two and a half hours settling.

Raw water will be introduced above the bottom of the tank at one side and will pass around a wooden baffle extending across the tank almost to the opposite side. The water will be taken off from the tank on the other side of this baffle through a floating outlet spout arranged to travel through a depth of ten feet from the top of the tank and connected to the eight inch supply line leading to the filters. A four inch blow-off valve and piping connection is located in the bottom of the tank for draining the tank to a tile sewer which will extend to a ravine east of the filter plant location.

The filter plant will be of a gravity type, located on the side of the hill half way between the settling tank and the storage tanks, with its base level with the top of the storage tanks. It will be equipped with two circular wooden filters, each fifteen feet in diameter and seven feet deep. Each will have an effective area of one hundred and seventy-six square feet, or a capacity of five hundred thousand gallons when operated at a rate of one hundred and twenty-five million gallons per acre per day. The filters will be covered with a frame building, twenty-four feet by thirty-eight feet interior dimensions, constructed upon a concrete foundation. The filters will rest upon four by six oak strips, spaced eighteen inches center to center and laid directly upon a six inch concrete floor which will cover the entire interior of the filter building.

The raw water will enter the filter through a six inch valve connection to the eight inch supply line from the settling basin and will be distributed over the surface from an overflow trough extending partly around the circumference of the filter at a height of eighteen inches above the surface. Water will be taken off from the filter through a manifold system consisting of a six inch header with one and one-fourth inch lateral pipes radiating therefrom and spaced six inches center to center on the bottom of the filter. In to this grid of pipes there will be seven hundred and twenty bronze strainer connections spaced six inches center to center. The filtering material will consist of ten inches of gravel and thirty-six inches of selected filter sand. The outlet pipe from each filter will be controlled by a rate controller which will limit the rate of operation of the filter to a one hundred and twenty-five million gallon rate. From the rate controllers the water passes through an eight inch filtered water main to one of the largest storage tanks nearest the filter plant and thence through the storage tanks into the existing supply main connections.

In cleaning the filters, water from the settling basin will be introduced into the strainer system by means of a six inch wash water connection and will be forced up through the filtering material to the wash trough located at the top and thence through an eight inch connection to the sewer line. No agiation is proposed, but it is intended to wash at a high rate, probably eight or ten gallons per square feet per minute. After washing the filter, the water first filtered will be wasted through a four inch connection to the sewer. A loss of head gage is to be provided for each filter to read the loss of head directly, so that the operator will know immediately when it is necessary to clean.

A by-pass line is provided around the filters, so that the water from the settling basin can be introduced directly into the storage reservoir without passing through the filters. The Greer Filter Company, who have prepared the plans for the filter plant and propose to install same, have guaranteed a bacterial reduction of not less than ninety-eight per cent when the bacteria in the unfiltered water is three thousand or more per c. c., and that when the number is less than three thousand, the average number in the filtered water shall not exceed one hundred per c. c., and shall meet the requirements of the State Board of Health. They propose to furnish with the filter plant a field equipment of testing apparatus and chemicals for making tests of the raw and filtered water and to instruct the operator how to make the necessary tests.

In order to obtain the full capacity of the storage tanks, a float and valve are to be provided on the smaller tank which will automatically close the inlet when it is full and allow the other two tanks to fill to their full capacity.

The continued prevalence of typhoid fever in Freeport demands the installation of a proper water purification plant. While there is at present some reduction in the number of bacteria due to infiltration through the cribs at the intake and through subsidence in the storage reservoirs, yet it is absolutely necessary to safeguard the public health of this community that an efficient filter plant should be installed which

will be operated in an intelligent and careful manner. It is to be noted that the water works company realizes that this will be a profitable investment, as it will increase the domestic consumption and will probably eliminate the use of the wells and springs which are now in constant use for drinking purposes and are not above suspicion. The water company has voluntarily submitted this application for the approval of a filtration plant and should receive the support of the borough officials in its efforts to furnish a pure supply.

The facilities for fire protection in a large portion of the borough appear to be inadequate. Through the center of the borough the hydrants are connected to the six inch supply mains and are sufficiently close together to furnish ample protection in times of fire. In other sections of the borough there are many hydrants connected with three and four inch mains and spaced eight hundred feet apart, so that during a severe fire it would be difficult to supply a sufficient amount of water. It would be advisable to increase the fire protection, either by constructing larger mains in these districts or by installing hydrants at more frequent intervals.

The plans submitted contemplate the by-passing of raw river water around the filter plant at intervals. As stated above there are three methods of by-passing water around the filters and by one of these it goes directly into the mains without any sedimentation or storage. Such by-passes are a menace to a water supply when the source of supply is contaminated and should be used only in the case of a great emergency. When so used all consumers should be notified in advance and advised to boil their drinking water.

The plans of the filters as submitted should furnish a plant of the highest type of efficiency, if intelligently operated. It is advisable in the installation of a filtration plant that the expert who installs it shall be entrusted with the general supervision of the plant for at least one year after installation or some one equally competent, in order that he may be fully responsible for the efficiency. It is impossible to allow a plant to be operated by one who is entirely ignorant of filtration without impairing the efficiency. It will probably be necessary to cover the storage reservoirs to prevent growths of algae.

It has been determined that the proposed water purification plant will not be prejudicial to public health, and a permit is hereby and herein granted therefor and for the extension of water pipes in the streets of the borough, under the following conditions and stipulations:

FIRST. That at the close of each season's work the water company shall file a plan of the water pipes laid during the year together with any other information in connection therewith that may be required, in the office of the State Department of Health, in order that the Commissioner of Health may be always informed of the extent of the water works system and the public use therof.

SECOND. That the filter plant shall be operated one year after installation under the direction of the expert who designed it, or some other competent expert. A full report of the initial test of the filter plant shall be submitted to the Commissioner of Health and thereafter the water company shall assist the State Department of Health in making such tests of the plant from time to time as may be desired.

THIRD. Weekly reports of the operation of the water works system and purification plant shall be kept on blank forms satisfactory to the Department of Health and copies thereof shall be filed with said Department. If at any time in the opinion of the Commissioner of Health, the water works system or any part thereof, or any water furnished thereby, has become prejudicial to the public health, or inefficient or defective, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

FOURTH. The by-pass provided for passing water around the filters directly into the mains must be kept closed and sealed under an arrangement satisfactory to the Commissioner of Health and only in some great emergency shall these valves be opened and used. If this is done the public must be immediately warned of the fact and the local and State health authorities notified.

FIFTH. At the completion of the work a complete set of plans of the new structures and all changes to existing structures shall be prepared and placed on file with the Commissioner of Health.

SIXTH. The Water Works Company shall notify the consumers of water who take the water from the supply pipe between the filter plant proposed and the pumping station, which consumers now get raw water, that all such water used for drinking and domestic purposes, shall be boiled, and the company shall construct, during the year nineteen hundred and nine, a connection from the filtered water supply and shall furnish the said consumers with filtered water.

SEVENTH. This permit carries with it the specific condition that the Freeport Water Works Company is authorized by its charter to do the things which it proposes to do as hereinbefore described. However, it is suggested, that the said company should find it advisable to have the undisputed limits of its water district defined by the Pennsylvania Water Supply Commission and that for this purpose an application should be made, as provided by law.

Harrisburg, Pa., September 2, 1908.

HOPEWELL TOWNSHIP, BEAVER COUNTY.

Jones and Laughlin Steel Company.

This application was made by the Jones and Laughlin Steel Company, of Pittsburg, and is for permission to construct a system of water works for the supply of water to the public on its own property, consisting of the village of Woodlawn, in Hopewell township, Beaver county, Pennsylvania.

The Jones & Laughlin Steel Company is constructing a new manufacturing plant, which will ultimately consist of coke ovens, blast furnaces, steel works, rolling mills and finishing departments.

This plant is being built at Woodlawn, a village in Hopewell township, Beaver county, Pennsylvania, along the Ohio River, about twenty miles down stream from Pittsburg.

In order to provide adequate habitations for the employes engaged in the construction and operation of this plant it has become necessary for the company to build houses to care for at least twenty-five hundred people. It is represented that this number of people will undoubtedly be increased to ten thousand or more by the time all departments of the plant are constructed and in operation. Before the Jones & Laughlin Steel Company began work at Woodlawn the village consisted of possibly one hundred inhabitants within the district immediately affected by the construction of this plant. The population now consists of nearly sixteen hundred persons, and in order to provide these people with convenient and sanitary habitations, the company has already constructed sixty-three blocks of double houses—one hundred and twenty-six dwellings in all—and fifty-one single and double modern houses—fifty-six dwellings in all.

To provide these houses with the necessary water supply, the company purposes to erect a pumping station, storage system and supply distribution.

The proposed pumping station is to be located two hundred and twenty-five feet up stream from the Ohio River dam number four on property belonging to the company and at the river harbor line. The sewer outlet into the river, temporary approval of which has been given by the Commissioner of Health, is at the mouth of Logstown Run below the dam. The said pumping station is laid out to provide for a population of ten thousand inhabitants and ample provision is made for additional pumps if this population should be exceeded.

The pump house is a circular structure fifty feet in diameter and its walls rest on solid rock foundation seventy-five feet below the surface of the ground and the floor of the motor room. The basement is to be the pump well and ports in the outer walls will provide an entrance for river water to the large pumping engines designed to furnish supply to the industrial plant. The pumps will rest on the floor twenty-four feet above the bottom of the well. This will be made water tight. Twenty-seven feet above this floor will be the operating floor of the pump house.

The pumps for the domestic supply are to be electric driven, vertical, triplex, deep well pumps, two in number, each of two hundred and fifty thousand gallons capacity in twenty-four hours, and they are to have a four inch suction into a twelve inch collecting main which is to extend up stream, reducing to ten inch, eight inch and six inch diameters, off of each size of which are to be two four inch branches, each branch terminating in an eight inch vertical pipe driven to solid rock from forty to fifty feet deep below the shores of the river. These driven wells have their tops slightly above the low or permanent level of the Government Dam. This structure, however, is collapsible—that is, it is provided with wooden sections which may be raised to a height of nine feet, so that the highest level of the dam will for the present submerge the driven wells nearly nine feet, if the information now in possession of the Department be accurate. However, the line of wells is back of the harbor river line and it is the purpose of the company to fill in the land many feet deep to this line. All piping in connection with the wells is flanged, but in case the joints should leak there would be a possibility of the sewage polluted water of the river flowing into the wells and contaminating them. Plans of the piping have not been submitted. The depth to which it is proposed to cover the wells is not known. The burying of the apparatus under the conditions obtaining is a doubtful expedient. The piping should be where it may be easily reached and inspected and repaired.

A test well showed a very copious flow of water in the sand layer on top of the rock and bacteriological and sanitary analyses of this water showed it to be satisfactory in quality.

The pumps are to discharge into an eight inch main and where the pipe crosses the railroad tracks a sixteen inch cast iron pipe is to be laid. At each end of this sixteen inch line under the tracks of the Pittsburgh and Lake Erie Railroad special fittings are to be provided in contemplation of additional branch lines, both from the supply and the distribution.

The rising main will feed the pipe system, overflowing into two closed top steel standpipes. Only a portion of the entire water supply will pass through these tanks. The elevation at the bottom of these tanks is to be one thousand and fifty-six. The elevation of the motor floor of the engine house is to be seven hundred and twenty-five. The highest flood line was at seven hundred and eleven and

one half. The dam when up is at elevation six hundred and eighty-four. It will thus be seen that a very good pressure will be maintained in the distributing system. Each tank is to be thirty feet in diameter and thirty-six feet high.

It has been determined that the proposed water works system and source of supply will not be prejudicial to public health and a permit is hereby and herein granted therefor, under the following conditions and stipulations:

FIRST: That at the conclusion of each season's work plans of the water pipe laid during the year shall be filed by the owner of the system in the office of the Commissioner of Health, together with such other information in connection therewith as may be required, to the end that the Department may always be informed of the extent of the water works and use of the system.

SECOND: The driven well piping and connections shall be provided with suitable means of access for inspection and repairs if this be found feasible, otherwise, upon monthly tests of the waters which shall be made by the company which shall file copies of such tests with the Commissioner of Health, revealing the presence of any sewage organisms, the company shall filter the water by apparatus to be approved by said Commissioner. It is the purpose of the State Department of Health to also make tests of the water and if at any time in the opinion of the Commissioner of Health, the water supplied by the company for drinking purposes is prejudicial to public health, then such remedial measures shall be adopted as the Commissioner of Health shall approve or advise.

THIRD: If called for, weekly reports of the operation of the water works system shall be made on blank forms satisfactory to the State Department of Health and copies thereof furnished to the said Department.

FOURTH: Satisfactory record plans of the piping in connection with the driven well system shall be filed with the Commissioner of Health.

Harrisburg, Pa., June 29, 1908.

HOUTZDALE, CLEARFIELD COUNTY.

Houtzdale Water Company.

This application was made by the Houtzdale Water Company of the borough of Houtzdale, Clearfield County, Pennsylvania, and is for permission to obtain a new source of supply of water to the public in the borough of Houtzdale.

It appears that Houtzdale borough is a small mining community located in the south central part of Woodward Township on Beaver Run which flows easterly through about the center of the borough. Beaver Run is made up of numerous mountain streams which have their source in the southwest of Houtzdale about three miles. It takes a northerly and easterly course passing through numerous small mining settlements and at a point about four miles to the east of Houtzdale it empties into Moshannon Creek, which is a tributary of the West Branch of the Susquehanna River.

Houtzdale is about fifteen miles south of Clearfield borough, the county seat of Clearfield County, and has direct railroad connections with same, a branch of the Cambria and Clearfield Division of the Pennsylvania Railroad passing through the center of Houtzdale, as does the New York and Pittsburg Central Railroad.

The borough is divided into two sections. The northern or principal section is built on the side of the hill, the summit of which is about the northerly boundary of the borough. The natural drainage of this section is to Beaver Run. The southern section is also built on the slope, but not so severe as the other section. The natural drainage is also to Beaver Run.

The chief industry is the mining of coal. There are a few small mines scattered in the outskirts of the borough. The larger mines are scattered about the surrounding township. Within the borough limits the upper coal measures have been pretty generally worked out. It is probable, however, in the future, the lower measures will be worked, as the authorities are holding out inducements to operators.

The principal mining company is the Berwind, White Company. This concern employs probably six hundred men in various mines throughout the township. There are no manufacturing plants within the borough limits.

The population has been decreasing. In eighteen hundred and ninety it was twenty-two hundred and thirty-one, in nineteen hundred it was fourteen hundred and eighty-two and at the present time it is estimated to be about fifteen hundred.

There are three hundred and twenty houses in the borough of which eight have percolating cesspools, eight have private sewers and the remaining number have shallow privy vaults for the reception of sewage. The sanitary conditions are generally poor.

The water company serves two hundred and seventy-two houses, the remaining forty-eight obtain their water supply from wells or private springs. There are twenty-five wells in use at the present time. They are dug and are subject to surface contamination to a greater or less degree.

The Houtzdale Water Company was chartered August sixteenth, eighteen hundred and eighty-seven for the purpose of supplying water to the public at Houtzdale and in the vicinity. In eighteen hundred and eighty-seven, the Houtzdale Water Company drilled a well, built a frame pumping station, constructed a reservoir and laid pipes throughout the borough, and water has been served to the community from this source to the present date.

A remarkable circumstance is the fact that the pumping station, well and reservoir are located to the north of the borough in Woodward township on a summit which overlooks the borough.

The well which is within the pumping station, is drilled six hundred and fifty feet deep and consists of an eight inch pipe driven to a depth of four feet. In this casing there is a five inch suction pipe about three hundred feet long. The elevation of water is two hundred feet below the surface. In the pumping station there is a thirty-five horse power and one forty horse power tubular boiler and two forty horse power horizontal steam engines.

From the drilled well, water is pumped by an old type, Jericho suction pump which is operated by a beam connected with the steam engines through a series of cog wheels. This pump has a four and three-quarer inch plunger and a thirty-two inch stroke, makes twenty-eight strokes per minute, discharges four gallons per stroke or one hundred and sixty-one thousand, two hundred and eighty gallons per day and is operated continuously. From this pump the water enters the eight inch supply main and flows through the piping system to consumers, the surplus backing into the reservoir. In all, there are about four and one-half miles of eight inch pipe reducing to three inch cast iron pipe laid through the borough. The reservoir is of masonry construction and is located about fifty feet to the north of the pumping station, is fifty feet in diameter by eight feet deep, capacity ninety thousand gallons. The elevation is about one hundred and seventy-five feet above the business section of the borough.

There are a number of dead ends in the piping system but fire hydrants are placed on them for flushing as well as for fire protection. The maximum daily consumption is about ninety thousand gallons per day.

The water company proposed to build an intake dam on a small mountain stream distant about four and one-half miles south of the borough. The site is in Center County on Mountain Branch, so called, of Moshannon Creek, which forms the boundary line between Center and Clearfield Counties. From the proposed dam the water will flow by gravity through an eight inch wooden pipe and connect to the present eight inch supply main at Hanna and Charles Streets in the central part of the town. Water will then pass through the present piping system and the sulplus will enter the existing reservoir.

The proposed reservoir will be built in a natural ravine, the sides will be given a uniform slope of one to one, the bottom will be excavated with a gradual, descending grade to the breast. The breast is to be of masonry construction, two and one-half feet thick, and while not shown on the plan, is to have wing walls and also a spillway. A twenty-four inch pipe through the bottom will provide means for drainage. The depth of water at the breast will be five feet. The surface area of the reservoir will be about thirty-seven hundred and fifty square feet, the average depth about four and one-half feet, the capacity ninety-seven thousand five hundred gallons, and the elevation about two hundred and twenty-three feet above the business section of the borough and fifty feet above the present reservoir.

The present reservoir will be provided with float and check valves to prevent overflowing of the same from the new reservoir.

On August the twenty-fifth nineteen hundred and eight, on the day of the Department's inspection it was estimated that the flow in Mountain Branch was approximately two hundred thousand gallons per twenty-four hours. The watershed above the reservoir site has an area of about three square miles, is not populated, and is mostly barren, due to numerous forest fires.

It appears that the present deep well supply is strongly impregnated with sulphur and at times is not fit to drink, so the consumers report. The water is discolored and even has an offensive odor as well as taste. The company wishes to discontinue the well for this reason and also to save the cost of pumping. If the new supply is approved, the Pennsylvania Railroad Company will make use of the pure mountain supply, which will be an additional source of revenue.

Because Houtzdale borough is more or less honeycombed with old mine workings, there is a possibility that sewage from the borough may reach the underground waters so that an abandonment of the driven well supply would remove any suspicions of the possibility of sewage pollution.

It has been determined that the proposed new supply will not be prejudicial to public health and a permit is hereby and herein granted therefor under the following conditions and stipulations:

FIRST: That on or before December first, nineteen hundred and eight, the water company shall submit a plan of the watershed to the Commissioner of Health showing all the streams and public roads on the watershed.

SECOND. Gates shall be placed on the new supply main to the town to prevent the shutting off of the water at any time and facilities for flushing the pipe line at the low points shall be put in. All provisions shall be made on all dead ends and at low points in the town system to drain the pipes.

THIRD. If at any time the water works system or any part thereof or the source of supply, in the opinion of the Commissioner of Health has beome a menace or prejudicial to public health, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

FOURTH. The Water Company may extend its pipe lines from time to time as necessity may require, but at the close of each season's work plans of such extensions shall be made by the company and filed in the office of the Department of Health so that the Commissioner of Health may always be informed of the extent of the water works system and public use thereof.

FIFTH. Detail reports of the operation of the water works system may be required at any time by the Commissioner of Health and this permit is issued with the understanding and stipulation that such report shall be made whenever required by the Commissioner of Health.

The attention of the Water company is called to the fact that this permit relates only to its charter territory. If the company wishes to supply water beyond its charter territory, an application for right to do so should be made to the proper State authority. The Commissioner of Health is not empowered to extend charter privileges.

Harrisburg, September 25th, 1908.

HUMMELSTOWN, DAUPHIN COUNTY.

Hummelstown Consolidated Water Company.

This application was made by the Hummelstown Consolidated Water Company of Hummelstown, Dauphin County, and is for permission to extend its water works in the borough of Hummelstown to obtain an additional source of supply and for approval of plans for the filtration of the water so to be supplied.

It appears that on August sixteenth, nineteen hundred and seven, the Commissioner of Health issued a decree to the Hummelstown Consolidated Water Company relative to plans for the improvement of its source of supply of water to the public in the borough of Hummelstown, in response to an application duly made and bearing date of June thirteenth, nineteen hundred and seven. The conclusions of the decree were as follows:

"In view of all the circumstances, I have determined that the proposed improvements would be prejudicial to the public health, and I do hereby and herein withhold approval thereof.

"I beg to suggest and advise the said water company that it employ a competent engineer and work up the details of that water purification plant best adapted to the economies and necessities of the case, bearing in mind the various matters set forth in the above discussion."

In response to this advice the company has engaged an engineer, detail plans have been perfected and they are the ones which have been submitted and are now under consideration.

The charter of the Hummelstown Consolidated Water Company limits the territory in which the company can supply water to the public and corporations to the borough of Hummelstown so it appears. Hence that part of the company's application relative to the extension of water works into Derry and Swatara townships cannot be considered. Relative to this matter, however, it is to be noted that on August sixteenth, nineteen hundred and seven, the Commissioner of Health issued a decree to the Rutherford Heights Water Supply Company of Swatara Township, Dauphin County, relative to a plan for obtaining a source of supply from the Eastmere Water Company. It appears that on July twenty-second, nineteen hundred and seven, the Commissioner of Health had issued a permit to said Rutherford Heights Water Supply Company, which, among other things, specified, "that before the proposed water works system be constructed and used, detail plans thereof shall be prepared and submitted to and approved by the Commissioner of Health as provided by law, and among other things, said plan shall include designs for a water purification plant." But the Rutherford Heights Water Supply Company could not install a filter and get water to the public in the village of Rutherford Heights quick enough to supply the people living there and hence it asked temporary permission to take water from the Eastmere Water Company. The latter corporation was chartered in eighteen hundred and ninety-nine to supply water to the public in the village of Eastmere, Swatara Township, and the water is purchased of the city of Harrisburg at the city line. The conclusions of the said decree of August sixteenth, nineteen hundred and seven, were as follows:

"The Rutherford Heights Water Supply Company wishes to furnish a pure supply to Rutherford Heights at the earliest practicable moment and desires to do this under permission of the Commissioner of Health, but said Commissioner of Health is not empowered to grant a permit which will operate to extend the powers conferred by the charter of said water company. The Rutherford Heights Water Supply Company's charter provides that the company shall confine its source to the Swatara Creek at the place shown on the plan submitted by said Company and on file in the office of the State Water Supply Commission, March thirteenth, nineteen hundred and seven. Therefore, unless the

petitioners obtain a modification of the Company's charter, the Commissioner of Health cannot approve of any source except the Swatara Creek. However, the Commissioner of Health could entertain a petition for an extension by Eastmere Water Company of its pipe line to Rutherford Heights and this extension could be granted under the condition that it be within the charter rights of the Eastmere Water Company.

"Therefore, I hereby and herein decline to approve the plans of the Rutherford Heights Water Supply Company for the obtaining of a source of supply from the Eastmere Water Company.

"The petitioners have two courses open to accomplish the end desired. First, for the Rutherford Heights Water Supply Company to obtain a modified charter; second, for the Eastmere Water Company to apply for permission to extend its pipe lines to Rutherford Heights."

On October twenty-seventh, nineteen hundred and seven, the Rutherford Heights Water Supply Company secured an amendment to its charter and it now has a right to take water from the Swatara Creek at the same point and use the same intake which is in use by the Hummelstown Consolidated Water Company. Therefore, the said Rutherford Heights Water Supply Company, like any other corporation within the borough of Hummelstown, may purchase its water of the Hummelstown Consolidated Water Company, and this is the way in which it is intended to introduce filtered Swatara Creek Water into the territory covered by the charter of the Rutherford Heights Water Supply Company.

In a like manner the Eastmere Water Company of Swatara Township may, if it chooses, purchase water of the Rutherford Heights Water Supply Company of said township.

On December third, nineteen hundred and seven, the Progress Water Company was granted a charter for the purpose of supplying water to the public in the Township of Susquehanna, Dauphin County, more particularly in the villages of Progress and Pleasant View which lie in the east and are suburbs of Harrisburg, the source of supply to be from Swatara Creek, at the same point at which the Hummelstown Consolidated Water Company obtains its water, and at which the Rutherford Heights Water Supply Company proposes to obtain its supply.

Thus it is seen that the territory to which the water filtered by the Hummelstown Consolidated Water Company is to be supplied (by the proposed plant herein under consideration) practically comprises all of Susquehanna and Swatara Townships besides the borough of Hummelstown.

At the present time the Hummelstown Consolidated Water Company takes its water supply from Swatara Creek at a point just below the built up part of the borough. The water is pumped to a standpipe near the pumping station, distant about six hundred feet. There is a dam across the creek just above the highway bridge and this dam diverts the water into a penstock leading to a mill which is owned by the water company and used as a water power house and electric light plant. Water wheels, two in number, have a total capacity of about three hundred horse power. An auxiliary steam plant for electric lighting purposes has been provided. The tail race extends down stream about a quarter of a mile to the creek. The company owns the land between the tail race and the creek and also other land in the vicinity. On it near the bank of the creek the standpipe is located.

There are two pumps, one is driven by water power and one is an auxiliary steam pump used when water power is not available. The capacity of each pumping engine is about five hundred thousand gallons daily. The eight inch force main terminates in a stand pipe which is one hundred feet high and sixteen feet in diameter. The base of this stand pipe is about forty feet above the creek and level or slightly below the village. The stand pipe when full gives a pressure of approximately forty pounds in the village. It has a capacity of one hundred and fifty thousand gallons.

The borough water consumption is about two hundred and fifty thousand gallons ranging from two hundred thousand to three hundred thousand gallons daily. During a fire the pumps must be speeded up to meet the extra service. Thus the fire protection service is very poor.

About all of the citizens of the town use the public supply. There are a few private wells.

The Swatara Creek is a muddy and turbid stream and at times contains considerable culm or coal dirt. It is also subject to sewage pollution. The city of Lebanon is on the watershed.

The proposed improvements comprise a water purification plant, new pumping machinery, a storage reservoir and a new pipe line.

The purification plant is to consist of a sedimentation basin, mechanical filters, filtered water basin and accessories.

New pumping machinery is to consist of two triplex pumps, water power driven, each of a million gallons capacity when working against a pressure of one hundred and eighty pounds. These engines are to lift the filtered water into the new storage reservoir. A two million gallon low lift pump is to be provided to raise the creek water into the sedimentation basin. A wash pump of a capacity of two and three quarter million gallons per day against a twenty-five foot head is to be installed.

These pumps will be operated by water power. To provide against break downs or low water there is to be erected a two million gallon steam pump for auxiliary purposes.

The storage reservoir is to be located on a hill in Swatara township near Rutherford Heights. Its elevation will be about three hundred and seventy feet above the pumping station and its distance approximately three miles. The rising main is to be twelve inches in diameter. After this reservoir is constructed the present stand pipe in Hummelstown will be abandoned. The reason for going out in Swatara Township for the site of the new reservoir is that this is the most available site at a sufficient elevation to give ample pressure for improved fire service in Hummelstown borough.

The plans show a re-inforced concrete storage reservoir, circular, one hundred and eighteen feet in diameter, twelve feet deep to the flow line and divided into two compartments of equal size. Approximately this reservoir will hold one million gallons. It is to have a concrete roof. The side walls are so designed that in the future, if necessary, the walls may be nearly doubled in height.

The water is to be introduced at one end and taken out at the opposite end of each compartment, both being at the bottom of the reservoir. At the outlet end there is to a vertical pipe whose top will be the top of the high water mark in the reservoir. It will connect with the drain and thus serve as a safety valve to prevent the overflowing of the reservoir.

The raw creek water is to be lifted from the pool in a quiet place above the dam to a vertical height of about sixteen feet into the sedimentation basin at pump house but outside of it. This structure is to be built of re-inforced concrete open on top and is to comprise two compartments, each twenty feet wide and forty feet long at the bottom and slightly more at the top. The depth to the top of the walls is to be sixteen and five-tenths feet. The water level is to be six inches below the top. The approximate capacity of each compartment is one hundred thousand gallons. Thus when both compartments are in use a subsidence of two hours is provided when the plant is being operated at its normal capacity of two million gallons per twenty-four hours. There is opportunity for the addition of two other compartments in the future.

The chemicals, alum ordinarily and soda ash when the river is acid are to be introduced at the pump and will be fed by gravity from tanks in the boiler room. There are to be two solution tanks for the alum and one for the soda ash. The solutions are to be fed into an orifice box in which a constant level is to be maintained by means of a float and butterfly valve. The outflow is to be made by a graduated orifice arranged to be easily adjusted by the operator.

The chemically treated water is to be admitted to the subsidence basins at the top. The water will rise through a vertical pipe six inches in diameter to a height of three feet above the high level mark in the reservoir and flowing over the top of the pipe will fall upon a wooden platform and thus be sprayed and aerated. The top of the vertical pipe is to be fitted with a flange twenty inches in diameter provided to spray the water out. Three such aerators are provided at the inlet end of each compartment. The splash board will float on the water. Twenty feet from each inlet end is to be a baffle board across the compartment sunk to about mid-depth. The water is to be drawn from the outlet end at the surface through a fixed skimming pan eight feet long, fifteen inches deep and one to three feet wide. Water will flow over the edges of this pan, weir fashion, and thence through a twelve inch pipe to the main feed pipe to the filter, the latter to be sixteen inches in diameter. The head on the filter will be about four and one-half feet, measured from the high water level of the subsidence basin to the high water level on the filters. There is a pump in the centre of each compartment to the subsidence basin and the drainage is to be into the tail race by means of a twelve inch drain.

The filters are four in number, each fourteen feet long by thirteen feet wide with a rated capacity of five hundred thousand gallons daily. They are arranged in pairs on either side of the pipe gallery, the floor of which is covered with concrete on which the valve stands will be placed. Below in the gallery the influent, wash and drain pipe are to be placed and the regulating apparatus. The filters are to be partly roofed over by re-inforced concrete cover. The gallery and inner ends of the filters are to be enclosed within the building. Below the filters is to be a clear water basin made of concrete masonry twenty feet wide and thirty feet long with longitudinal partition walls supporting the inner ends of the filters and the pipe gallery. These walls will have openings through them. The capacity of this clear water basin is forty thousand gallons. This will be the pump well and thus a half hour pumpage will be on hand when the plant is operated at the two million gallon rate.

The sand in each filter is to be sharp fracture spherical grain, pure quarts sand, effective size about four-tenths millimeters with a uniformity of co-efficient of one and five-tenths. It is to have a depth of about thirty inches and rest on ten inches of gravel, ranging from a quarter to an eighth of an inch in diameter. This is to rest on the manifold system which is embedded in the concrete on the bottom of the filter and consists of an inch by twelve inch casting and two inch lateral pipes six inches apart and fitted with improved conical strainers six inches on centres.

There will be four feet of water on the sand at high water. The water is to be introduced on the filter through two parallel troughs, the head being maintained by a float and butterfly valve on the inlet pipe. The troughs are twelve inches wide, fifteen inches deep and semi-circular on the bottom and extend across the entire length of the filter and the lip of these troughs will be two feet above the sand line. The effluent from each filter will pass directly to the filtered water basin below, but there is to be a Norwood controller on each effluent pipe which will work under water and will be capable of regulation by means of which the speed at which the filter is operated may be regulated uniformly within certain limits.

The cleaning of the filter unit is to be accomplished by pumping filtered water back through the strainer system at a very high rate, probably six times the rate of filtration. It is expected that this high rate will prove as efficient as the combined air and water in common practice. The first filtered water after washing will be drained to the sewer which drain will also take the overflow pipe placed at the high water mark on each filter to obviate accident. The sewer will empty into the tail race which is to be directly below the clear water basin.

This tail waste is a new construction and is to be excavated from the present mill northerly a short distance to the creek in order to obtain the full benefit of the head to provide drainage facilities and to increase the head on the turbines. The walls of the clear water basin will be extensions of the walls of the new tail race and the space below the concrete bottom of the clear water basin which is to form the top of the new tail race underneath the filter plant will ordinarily be about two feet above the water line in the race. However, during flood and freshets the back water will rise nearly if not quite to the top of the clear water basin. Hence care must be taken that the filtered water well be constructed so as to make it water tight.

The layout is of modern design and well adapted to purify the Swatara Creek water provided chemicals are used and the plant be operated intelligently. However, the works should be constructed under the supervising direction of the expert who designed them or some one equally skilled in this branch of engineering.

The plant also to be operated for a period of twelve months under the supervising direction of the designer during which time the officers of the company or the attendants at the plant should be thoroughly schooled in the methods of operation and the adjustment of chemicals to the requisite treatment of the water in its varying quality.

The Hummelstown Consolidated Water Company purposes to sell filtered water to the three other water companies whose charters give them the right to take water from the same point in Swatara Creek. Approval of the plan would be withheld if these said three companies intended to take this water from the rising main or reservoir of the Hummelstown Consolidated Water Company in Swatara Township because the charter of said water company does not permit it to sell water in this territory. However, within the charter rights the proposed plans furnish a practicable scheme for the supplying of a pure and wholesome water to all of the villages and towns along the Philadelphia and Reading Railway between Hummelstown and Harrisburg.

It has been determined that the proposed improvement will not be prejudicial to public health and a permit is hereby and herein granted therefor and for the extension of the water works system in the borough of Hummelstown within the chartered rights of the Hummelstown Consolidated Water Company under the following conditions and stipulations:

FIRST: On completion of the proposed purification plant reservoir and other improvements the water company shall file with the State Department of Health complete and full detail plans of the same as built, showing all valves, pipes and appurtenances, together with any other information in connection therewith required by the Commissioner of Health.

SECOND: At the close of each season's work the company shall file a plan of the pipes laid during the year in the office of the State Department of Health, together with such other information in connection therewith as may be required by said Commissioner.

THIRD: The filter plant shall be operated under the responsible direction of the expert who shall erect the same for a period of twelve months in order that the water company's attendants may be afforded a reasonable time in which to become thoroughly schooled in the responsible duties of efficiently operating the water purification works. A full report of the intitial test of the plant shall be submitted to the Commissioner of Health and thereafter the water company shall assist the State Department of Health in making such tests of the plant from time to time as may be found desirable. If necessary, the Commissioner of Health may prescribe standards of efficiency and make regulations for the operations and maintenance of the plant and the entire water works system.

FOURTH: Weekly reports of the operation of the water works shall be kept on blank forms satisfactory to the State Department of Health and copies thereof shall be filed with said Department. If at any time in the opinion of the Commissioner of Health, the water works system, or any part thereof, or any water furnished thereby, has become defective, or inefficient, or prejudicial to public health, then such remedial measures shall be adopted by the water company as the Commissioner of Health may advise or approve.

FIFTH: The introduction of raw creek water into the street main system or anywhere, except into the filter plant, is absolutely prohibited. The plant being operated continuously and the storage on the hill being one million gallons, necessity does not exist for an emergency connection between the pumps and the street main, more especially since there is duplicate pumping machinery. The interests of the public health demand that all connections now in existence by means of which raw creek water is delivered to the water works system shall be absolutely cut off and put out of commission, when the improvements herein approved have been installed.

SIXTH: There shall be an attendant at the filter plant whenever the same is in operation.

SEVENTH: The drainage from the filter plant shall, if ever required by the Commissioner of Health, be otherwise disposed of than into the creek.

Harrisburg, Pennsylvania, January 16th, 1908.

JOHNSTOWN, CAMBRIA COUNTY.

Mr. Jerry Alwine.

This application was made by Jerry Alwine of Johnstown city, Cambria county, Pennsylvania, to construct water works and supply water to the public in that part of the Eighth Ward of Johnstown City formerly comprising the Borough of Roxbury.

It appears that that part of the Eighth Ward of Johnstown City which was previously the borough of Roxbury and which contains the straggling residential settlement still known by that name on the outskirts of Johnstown, is in the extreme southwestern part of the city in the valley of Stony Creek, which rises to the south in the Allegheny Mountains in Somerset county and follows a general northerly course to a point about two miles below and north of the Eighth Ward, where it joins the Little Conemaugh River in the heart of Johnstown forming the Big Conemaugh River. North of Roxbury is Grubtown, also in the Eighth Ward, while to the south is Ferndale borough and to the west Upper Yoder township.

It is the general practice in Roxbury to dispose of sewage in common privies and perhaps in a few cesspools and by discharging waste water into the street gutters. Previous to the installation of the water works under consideration, the entire domestic water supply was obtained from wells, most of which were dug. Many of these wells, it is reported, dry up during hot weather.

During the summer of nineteen hundred and eight the Johnstown Water Company installed in Roxbury a pumping station, distributing tank and about two miles of distributing pipes, in order that it might commence in the fall of nineteen hundred and eight to furnish water pumped from its low service mains for the use of the inhabitants of Roxbury.

Cherry Run rises about a mile west of Roxbury in Upper Yoder township and flows easterly in a deep ravine to the settlement, through which it follows a northerly course parallel to Stony Creek but separated therefrom by a distant hill. The run finally enters Stony Creek through Grubtown.

The water works for which a permit is asked have already been installed and water was supplied to the public thereby during the summer of nineteen hundred and eight, the applicant at that time being ignorant of the necessity of obtaining a permit. The principal supply is obtained from a spring which is located high on the southern slope of the ravine of Cherry Run and just southwest of the settlement of Roxbury, two hundred feet south of Joseph street, in Upper Yoder township. The spring is within a few hundred feet of the crest of the hill and less than one hundred feet below it. A field on the summit may be either cultivated or used as a pasture, but there are no buildings of any description above the spring, which is in a grove and surrounded by an acre of ground owned by the petitioner. The surface formation is sandstone. The water from the hillside above is to be diverted from the spring by means of a ditch.

A slight excavation has been made in the hillside around the spring and the face of this excavation has been walled up. Immediately in front of this wall is a water-tight masonry tank about nine feet square by three and one-half feet deep, with a frame roof. Adjacent to this tank is a water-tight masonry reservoir, twenty feet wide, fifty feet long and five and one-half feet deep, also covered with a frame roof. In the bottom of the tanks are two two inch flush pipes and there is also a two inch flush pipe leading from the bottom of the reservoir at the southeastern corner. At present the water from the spring is piped directly into the reservoir, but when the arrangements are completed a pipe will convey the water from the spring to the small tank provided to catch any sediment and from the tank the water will overflow into the southwestern corner of the reservoir. From a point in the southeastern corner of the bottom of the reservoir close to the drain pipe a two inch supply pipe protected by a sieve extends northeasterly through private property and across the city line about five hundred feet, into Derby street of Roxbury. This system includes about three thousand feet of two inch and one and a quarter inch galvanized iron pipe. There is a

valve at the reservoir, so that the supply may be shut off. Although no blow-offs for the draining of the pipe system have been installed, it is understood that the applicant intends to place such blow-offs in the pipe lines at low points. Water is furnished to, about thirty dwellings, perhaps a population of one hundred and fifty, less than half the total population in this little district. A one inch pipe is to lead from the northeastern corner of the reservoir and furnish water to several dwellings on Joseph street within three hundred feet of the reservoir.

The applicant reports having obtained from the Mayor of the City of Johnstown such permits as were necessary for laying the pipes in the streets. He has no franchise from the city for supplying water to the public.

The petitioner has a second spring eight hundred feet southwest of the Joseph Street Spring and just south of Berkley Street, also in Upper Yoder township and in the head of a small ravine which opens northeasterly into the valley of Cherry Run. During the summer of nineteen hundred and eight water was furnished from this spring through a one and a half inch pipe about fourteen hundred feet long to Roxbury Park, a summer amusement resort immediately south of Roxbury in Upper Yoder township.

The land above the spring is under cultivation. There is one dwelling owned by a Mr. Harry Berkley, on the summit of the divide between this valley and the next valley to the south. From this dwelling domestic waste water is discharged on to the surface of the field about four hundred feet above the spring. However, the surface wash will carry this sewage and the drainage from the public road past the spring which is south of the bottom of the ravine.

At present the spring flows from the steep hillside into an open water-tight masonry reservoir, twenty-seven feet by thirty-one feet in plan and seven feet deep. The one and a half inch supply pipe to the park leads from the bottom of the reservoir being protected by a sieve. A two inch drain pipe also leads from the bottom of the reservoir. It is proposed to wall up the spring and put a roof on the reservoir and protect both of them from surface wash. It is further proposed to lay a suction pipe from this reservoir to a pump to be located in a slaughter house owned by the petitioner just below the spring and to lay a one and a half inch force main from this pump to the Joseph Street reservoir, so that both springs may be used to furnish water to this latter reservoir and the distributing system supplied thereby. This Berkley Street spring is located in the upper end of a ten acre tract owned by the petitioner.

The water to be obtained from these springs after the completion of the arrangements for their protection from surface wash should almost unquestionably be pure and of a good quality. Although up to the time of the Department's investigation on September tenth, nineteen hundred and eight, the Joseph Street Spring had furnished and adequate supply to all the consumers dependent upon this source while many other sources in the vicinity had failed, it does not seem that a much greater population could be safely dependent upon this source, even when augmented by pumping water from the Berkley Street Spring. Probably the water works will not be greatly extended. It appears that the local wells furnish an inadequate supply of water and are also suspicious sources in view of the practice of disposing of sewage in privies and on the surface of the ground. It does not appear that the Johnstown Water Company's having extended its mains into Roxbury is any reason for denying a permit for the construction of the water works herein considered.

It has been determined that the water works and the sources of supply will not be prejudicial to public health, and a permit is hereby and herein granted therefor under the following conditions and stipulations:

FIRST: No more water shall be furnished to the public from the Berkley Street reservoir until it has been roofed over, the spring walled up and protected from chance or malicious pollution and both the spring and the reservoir adequately protected from surface wash.

SECOND: The petitioner shall cause inspections to be made of the areas on the hillsides above the two reservoirs as often as necessary and shall immediately inform the Department of the erection and occurrence of any possible source of pollution on either of these water sheds, and of the disposal of the sewage at the house above the Berkley Street reservoir becoming a menace to this source of supply, if such should ever be the case.

THIRD: When it is desired to install the pipes and pump, to force the Berkley Street water into the Joseph Street reservoir, complete plans of the pipe lines, pumping station and connections shall be filed with the Commissioner of Health. At the end of each season's work plans and such other information as may be required showing the extensions of the distributing system made during the year shall be filed with the Commissioner of Health in order that the said Commissioner may be always fully informed of the extent of the water works and its use.

FOURTH: On or before January first, nineteen hundred and nine, blow-offs shall be installed at low points in the pipe system, by means of which, if necessary, all the water may be drained from the pipes, and a plan showing the locations and sizes of these blow-offs shall be filed with the Commissioner of Health

FIFTH: It is the intention of the Department to collect samples of water for analysis from time to time from the various parts of the water works and the petitioner shall render such assistance in this work as may be necessary.

SIXTH: Detail reports of the operation of the water works shall be kept on blank forms satisfactory to the Commissioner of Health and copies thereof shall be filed with the said Commissioner of Health.

SEVENTH: If at any time the water works or any part thereof or the water supplied thereby shall become prejudicial to the public health. then such remedial measures shall be adopted and enforced as the Commissioner of Health may approve, suggest or advise.

EIGHTH: It is expressly stipulated that the petitioner in conducting his business and extending his water works shall comply with the provisions of all laws pertaining thereto.

Harrisburg, Pa., October 15th, 1908.

JOHNSTOWN, CAMBRIA COUNTY.

Johnstown Water Company.

This application was made by the Johnstown Water Company of the City of Johnstown, Cambria County, and is for permission to extend its water-works system and to obtain an additional source of supply.

It appears that the city of Johnstown is located on the main line of the Pennsylvania Railroad, twenty-five miles west of the great divide between the Susquehanna River and the Ohio River basins at the junction of the Little Conemaugh River and Stony Creek. These streams form the Big Conemaugh River which flows westerly from Johnstown into the Kiskiminetas River, the latter emptying into the Allegheny River at Freeport borough, Westmoreland county.

Johnstown is a thriving manufacturing community, the home of the Cambria Steel Company. While there are numerous other manufacturing plants in the locality, the manufacture of iron and steel and the mining of coal, principally of the Cambria Steel Company, constitute the most important enterprise. The city is on the western edge of the Cambria-Somerset district of the upper bituminous coal measures. Johnstown had a population of twenty-one thousand, eight hundred and five in eighteen hundred and ninety; thirty-five thousand, nine hundred and thirty-six in nineteen hundred and has about sixty thousand at present. The community centering around Johnstown comprises a considerably larger area than the city itself. In the surrounding boroughs and townships there are probably twenty thousand people, considerably scattered, due to the peculiar topography.

The Big and Little Conemaugh and Stony Creek are in deep, steep sided valleys. The Little Conemaugh enters the city from the northeast, having its source near the summit of the Allegheny Mountains and draining a very rugged, mountainous area. Stony Creek rises in the Allegheny Mountains to the south in Somerset county and flows northerly to its junction with the Little Conemaugh in Johnstown. The valley of the creek in the city and for a short distance above has a comparatively wide, flat and low lying bottom. The Big Conemaugh River flows out of the city to the northwest in a rugged valley similar to that of the Little Conemaugh. It is in this valley along the banks of these two streams that the main line of the Pennsylvania Railroad winds from the east westerly toward Pittsburgh. The works of the Cambria Steel Company extend throughout the city from east to west, also in the valley of the Big and Little Conemaugh Rivers, in places on one bank and elsewhere on the other. A private railroad of the company connects the various parts of the works and its neighboring coal mining operations.

The old town, now the business section, comprising the first, second, third and fourth wards of Johnstown, is located on the flat ground in the fork between Stony Creek and the Little Conemaugh. To the south across Stony Creek, are the fifth and sixth wards known as Greenville. West of these districts on a high bluff, is Westmont borough, a residential district reached by an incline plane. Further up Stony Creek on its eastern bank, is the seventh ward of Johnstown, known as Hornerstown. East of this, on the hillside and the summit above are the small boroughs of Dale and Daisytown. Further up-stream, west of Stony Creek, is the eighth ward of Johnstown, consisting of Grubtown, adjacent to the stream, and further to the south Roxbury, originally a borough by that name. Beyond Roxbury along Stony Creek is the borough of Ferndale. Opposite these places on the east bank, is the seventeenth ward of Johnstown known as Moxam. Stony Creek follows a tortuous course between these wards and boroughs. Upper Yoder township lies to the west of this district and Stony Creek township to the east.

In the valley of the Little Conemaugh on the south bank of the stream and east of the business district are the Ninth and Tenth Wards of Johnstown, originally Conemaugh borough and still known as such. Northeast of this district across the stream is the eleventh ward, known as Woodvale, and still further upstream

are the boroughs of East Conemaugh and Franklin respectively on the north and south banks of the Little Conemaugh River. These wards and boroughs in the valley of the Little Conemaugh are bounded on the north and south respectively by East Taylor and Conemaugh townships. The twelfth and thirteenth wards known as Prospect are on the north bank of the Little Conemaugh opposite the business district and junction of the streams and extend up the hillside. To the north of Prospect is the small borough of Rosedale in the valley of Hinckston Run.

Below Prospect in the valley of the Big Conemaugh on its southern bank are the fifteenth and sixteenth wards of Johnstown, known as Cambria City and across from them on the north bank is the fourteenth ward Minersville. Further up stream are the eighteenth, nineteenth and twentieth wards, known as Morrellville on the southwestern bank of the river and in the valley of St. Clair Run, and the twenty-first ward, Coopersdale on the northeastern bank. The wards in the valley of the Big Conemaugh are bordered on the north by West Taylor township and on the south by Lower Yoder township.

The city is more or less completely sewered by public, combined sewers receiving both sewage and storm water and discharging into the various streams. Above the city these streams are contaminated by mine drainage and are yellow in appearance. The river below the city is foul and blackish because of the sewage and industrial wastes discharging into it.

The Johnstown Water Company was incorporated by an Act of the General Assembly entitled "An Act to Incorporate the Johnstown Water Company" approved April eleventh, eighteen hundred and sixty-six (P. L. seven hundred and twenty-three) and letters patent of the Commonwealth were issued to it June fourteenth, eighteen hundred and sixty-seven and July thirty-first, eighteen hundred and eighty-eight upon the Water Company accepting the constitution of the Commonwealth and the Corporation Act of eighteen hundred and seventy-four. The purpose for which the company was chartered is the introducing from some convenient source a sufficient supply of pure, wholesome water into the boroughs of Johnstown, Conemaugh, Millville, Prospect, Cambria and vicinity in Cambria county, Pennsylvania. All these boroughs are now parts of the city of Johnstown. The Johnstown Water Company, upon its organization, took over the water works of the older Johnstown Water and Gas Company.

The Stony Creek Water Company was incorporated September seventh, eighteen hundred and eighty-eight to supply water for the public at Moxam in Stony Creek township and to persons, partnerships and associations residing therein and adjacent thereto as may desire the same. The Johnstown Water Company is reported to have purchased all the property, stock and franchises of the Stony Creek Water Company about eighteen hundred and ninety.

The Manufacturers Water Company was incorporated February nineteenth, nineteen hundred for the supplying of water for commercial and manufacturing purposes. This is still an independent company.

The Morrellville and Cambria Borough Water Company was incorporated October eleventh, eighteen hundred and eighty-eight for supplying water to the public at the borough of Cambria and surrounding township of Lower Yoder and to persons, partnerships and associations residing therein or adjacent thereto as may desire the same. This company furnishes water to about three thousand consumers among the seventeen thousand inhabitants of the fifteenth, sixteenth, eighteenth, nineteenth and twentieth wards of Johnstown and to several industrial establishments. The sources of supply are Struyer Run, a tributary of St. Clair Run, and a drilled well near the intersection of Chandler Avenue and F Street in the district known as Morrellville. This is also an independent company.

The Eighth Ward Water Company of Johnstown, Pennsylvania, was incorporated April seventeenth, nineteen hundred and six for the supply of water to the public in that part of the eighth ward of the city of Johnstown formerly constituting the borough of Roxbury. This company has as yet, installed no works and is reported to have no prospective supply or intention of becoming active.

A private individual, Jerry Alwine, is supplying water for domestic purposes to about one hundred and fifty consumers in that part of the eighth ward known as Roxbury, and his system has been approved by the Commissioner of Health. The sources of supply are neighboring springs.

Quite a number of drilled wells in the heart of the city are used as sources of water supply by industrial establishments, hotels and stores, and there are many individual wells both dug and drilled still in use in the outlying districts, particularly in the higher parts, to many of which the mains of the Johnstown Water Company do not extend.

The Johnstown Water Company obtains its supply from six tributary surface streams widely separated in the three valleys radiating from Johnstown, one of these sources, Salt Lick Run, being the subject of one of the applications herein considered. The dams from which the waters of these various streams are taken vary from mere intakes to an impounding dam of one hundred and thirty million gallons capacity. The various sources are Mill Creek, Dalton Run, St. Clair Run, Wild Cat Run and Salt Lick Run, and the intakes are at an average distance of five miles from the center of Johnstown. An auxiliary supply may be and has been obtained from the Manufacturers Water Company both from Hinckston Run and Stony Creek.

Mill Creek a tributary of Stony Creek furnishes one of the principal and oldest supplies. On it, southwest of Johnstown, are two impounding dams in Upper Yoder township, the lower with a capacity of thirty-two million gallons, the upper ninety-seven million gallons. The lower dam is used only as a last resort, being too low to furnish water at a satisfactory pressure. The watershed above the upper dam is about four square miles, perhaps five square miles above the lower dam, all in Upper and Lower Yoder townships. The country is very hilly and largely wooded, and on the drainage area there are eight or more farmsteads with a population of perhaps sixty persons.

The twenty-four inch pipe from the lower reservoir is reduced after a short distance to a twenty inch pipe which extends in the valleys of Mill Creek and Bens Creek and Stony Creek, of which the former are tributaries, about three miles to the city line. In the southern part of the city this main is divided into a twelve inch and a sixteen inch main which extend to the central part of the city respectively on the west and east sides of Stony Creek. A thirty-six inch pipe line half a mile long connects the upper Mill Creek Reservoir with the twenty inch main from the lower.

Dalton Run, appropriated subsequently to the Mill Creek supply, now furnishes much of the city's water. On it, southwest of Johnstown and beyond Mill Creek, is a one hundred and thirty million gallon impounding reservoir in Conemaugh township, above which reservoir is a hilly, largely wooded watershed of four or five square miles in Conemaugh and Upper Yoder townships. In this drainage area there are said to be at least eight farmsteads and a population of perhaps sixty persons. From this reservoir a twenty inch pipe line extends in the valleys of Dalton Run and Bens Creek of which Dalton Run is a tributary, about three miles to its point of connection with the pipe from Mill Creek where said pipe emerges from the valley of Mill Creek into the valley of Ben's Creek.

St. Clair Run a tributary of Big Conemaugh furnishes a considerable supply to the western part of Johnstown. On it, west of the northern part of the city, is a dam with a capacity of fifteen million gallons in Lower Yoder township, above which dam there is in Lower and Upper Yoder townships, a largely wooded, hilly watershed of about five square miles very similar to the sheds of Dalton Run and Mill Creek. A twelve inch pipe line extends from this dam about a mile in the valley of St. Clair Run to the city line, and thence two miles or more along the south side of the Conemaugh River through Johnstown to the heart of the city, the system being intimately connected with that fed by Mill Creek and Dalton.

Laurel Run and Wild Cat Run tributaries of Big Conemaugh furnish the remainder of the supply to the western part of the city. On Laurel Run north of the western part of the city and in West Taylor township, is a nine million gallon reservoir above which, in West Taylor and Jackson townships, is a largely wooded, hilly watershed of about eighteen square miles, upon which there are reported to be thirty farmsteads and dwellings, about ten within one-half mile of the reservoir. Three or four dwellings particularly menace the supply, being less than one-fourth of a mile above the reservoir and, with their outbuildings, line both banks of a small tributary.

A sixteen inch pipe line extends from this dam about eighteen thousand feet in the valleys of Laurel Run and the Conemaugh River to Coopersdale, the twenty-first ward. The sixteen inch pipe continues up the northern bank of the Conemaugh River through the twenty-first ward and West Taylor township into Minersville, the fourteenth ward. Here a twelve inch pipe was laid across in the bed of the Conemaugh connecting the Laurel system with the St. Clair Run system at the foot of Third Avenue in the fifteenth ward. The connection was made in nineteen hundred and seven.

On Wild Cat Run, a tributary of Laurel Run, there is in West Taylor township, a small intake dam from which a pipe line connects with the one from Laurel Run and above which in West Taylor and Jackson township, is a wooded watershed of about two square miles, on which there are reported to be but one or two habitations.

Salt Lick Run was used as a source of supply by the Johnstown Water Company in the fall of nineteen hundred and seven. There is a small intake dam on the run about one-fourth of a mile north of its junction with the Little Conemaugh River. A six mile, twenty inch pipe line in the valley of the Little Conemaugh conveys the water into Johnstown.

The distributing system in the valley of Stony Creek, fed principally from Mill Creek and Dalton Run, covers pretty completely this part of Johnstown and also extends eastward from that part known as Hornerstown into Dale borough and Walnut Grove village in Stony Creek township. There are also a few distributing pipes in Ferndale borough. At the foot of the bluff west of that part of the city known as Greenville is a pumping station which takes water from the distributing system in the said Greenville district through a six inch suction pipe and forces it through an eight inch force main eighteen hundred feet long to a distributing reservoir on the bluff in the southeastern part of Westmont Borough, which is supplied with water from this reservoir. The Water Company also maintains a pumping station in the district known as Prospect, at the foot of the hill north of the Little Conemaugh and opposite the business section. The suction is a four inch pipe connected with a twelve inch main laid across the

Little Conemaugh in its bed from the central part of the city. This pumping station forces water from the low service distributing system through a force main of four inch, six inch and ten inch pipes twelve hundred feet long, to a small distributing reservoir known as the Lower Prospect Reservoir. There is also a force main from this pumping station composed of nineteen hundred feet of six inch to eight inch pipe leading to the Upper Prospect reservoir. From these two reservoirs water is furnished to Prospect. During the summer of nineteen hundred and eight a pumping station was erected by the Johnstown Water Company at the foot of the hillside in the western part and that part of the eighth ward, previously Roxbury. The pumping station is reported to have a capacity of two hundred and sixty thousand gallons per twenty-four hours. It is intended to put the pumping station in operation in the fall of nineteen hundred and eight. Water will be taken from the low service distribution system and forced into a seventy-seven thousand gallon tank on the hill west of the pumping station from which tank it will be distributed through about two miles of four inch, six inch and eight pipe laid during nineteen hundred and eight in the built-up part of Roxbury in the eighth ward of Johnstown.

The distributing system in the valley of the Big Conemaugh, fed principally by St. Clair Run, Laurel Run and Wild Cat Run, is reported to be restricted practically exclusively to the territory within the city.

The distributing system in the valley of the Little Conemaugh is not so extensive as those in the other valleys, and is reported to be restricted within the city limits. Therefore, a considerable part of the supply brought through this valley by the twenty inch pipe from Salt Lick Run is probably furnished to the distributing systems supplied more directly from the other sources.

There are fire plugs throughout the distributing system and also quite a number of blow-offs by means of which the pipes may be more or less completely flushed out. Facilities are also provided for more or less effectively flushing the reservoirs.

Stony Creek furnishes a supply to the Manufacturers Water Company. From the intake dam on the creek at Border Station of the Rockwood and Johnstown Branch of the Baltimore and Ohio Railroad in the valley of Stony Creek, a thirty-six inch pipe line extends seven miles down stream to the heart of Johnstown, the lower part of this pipe line paralleling the pipe line from Dalton Run and Mill Creek. There is a cross connection and controlling valve between this thirty-six line and the twenty inch Mill Creek line in Ferndale just south of Johnstown and a similar connection and valve between the Stony Creek pipe and the sixteen inch branch of the Mill Creek pipe line in Hornerstown at the corner of Cherry and Horner Streets. One or both of these connections may be and have been used to furnish Johnstown with Stony Creek water upon the other sources failing because of drouth. The watershed of Stony Creek above the dam at Border Station has an area of three hundred and thirty square miles supporting a population of about thirteen thousand, two hundred and twenty-five, in parts of ten townships and two boroughs, all in Somerset county. There are also thirty mining operations along the streams, and the creek above the intake has the appearance of being polluted with mine drainage.

During the summer of nineteen hundred and eight Johnstown and its vicinity experienced a drought unprecedented in the history of the water company. During July, the storage of the Water Company was seriously depleted, due to lack of rainfall. On July thirty-first what water remained in the Dalton Run reservoir was flushed out and wasted and on August second the flow of the stream was turned into the pipe line. It became apparent that the resources of the Johnstown Water Company would be exhausted.

Instead of resorting to Stony Creek water, as in previous droughts, the Water Company made an agreement with the Cambria Steel Company for the use of the water of Hinckston Run. Northeast of the city on this run, which is here the boundary line between West Taylor and East Taylor townships, is a one billion gallon reservoir above which the run has a drainage area of ten and nine-tenths square miles supporting a population of about seven hundred. Although there are considerable wooded areas, the greater part of the territory is under cultivation. The reservoir is reported to have a depth of seventy-five feet and on September eleventh at the time of the Department's investigation, the depth of the water remaining in the reservoir was about fifty-three feet, at which depth it is reported to hold about five hundred million gallons. The Cambria Steel Works was reported to be drawing but a small quantity from the reservoir at the time, and it was estimated that the water stored would last the city for a period of six weeks at least, if rainfall did not bring relief from the drought. A twenty-four inch pipe line extends from the dam down the valley of the run through Rosedale Borough and enters the city in Minersville. Here there is a sixteen inch connection with a valve between this pipe line and a sixteen inch pipe line of the Cambria Steel Company which is in reality an extension of the sixteen inch pipe line from Laurel Run and which extends from Minersville upstream along the northern bank at least to a point opposite the ninth and tenth wards, the district known as Conemaugh Borough where there is a connection across the river into these wards. On September second, nineteen hundred and eight, under the agreement between the Water Company and the Steel Company, the water from Hinckston Run was turned into the Water Company's mains. This was done by opening the valve in the sixteen inch connection between the twenty-four inch

pipe from Hinckston Run and the sixteen inch pipe along the northern bank of the river, which is part of the system supplying the Steel Company. The ninth and tenth wards distributing system was connected by a ten inch temporary pipe with the pipe of the Steel Company which, as already mentioned, here crosses the Little Conemaugh from the sixteen inch main on the north bank. By means of a twelve inch temporary connection, this same sixteen inch main was connected with the twelve inch pipe which crosses the Little Conemaugh from the central part of the city and furnishes the supply to the four inch suction of the Prospect Pumping Station and also to a small settlement called Millville on the north river bank at the foot of the hill on which Prospect is located. Moreover, the sixteen inch main of the Steel Company being a continuation of the sixteen inch main from Laurel Run, the water from Hinckston Run was for a time turned into the distributing systems of the western part of the city both north of the river and also south of the river, by means of the twelve inch connection crossing the Big Conemaugh at Third Avenue, Cambria City. However, it was found that the water from Hinckston Run was supplied at such a pressure that it backed up and filled the Laurel Run reservoir so that on September fifth the Hinckston Run supply was shut off from the entire western part of the city except in so far as it might find its way into these districts through the central part.

On September third, nineteen hundred and eight the water remaining in the Upper Mill Creek reservoir was flushed out and wasted and on September fifth the stream flow was turned into the pipe line. At night-fall the upper Mill Creek reservoir was shut off and the stream in the lower Mill Creek reservoir which was empty but had not been flushed out, was turned into the pipe line.

It was reported at the time of the Department's investigation in September, that practically only the streams flow was being obtained from St. Clair Run but the reservoir had not been flushed out.

On September eleventh, nineteen hundred and eight, it was reported that the daily supply furnished by the Johnstown Water Company consisted of about four million, five hundred thousand gallons from Hinckston Run, about one million gallons from Dalton and Mill Creek together and about one million five hundred thousand gallons from Salt Lick Run, and that Laurel Run, Wild Cat Run and St. Clair Run together were furnishing a fairly plentiful supply to the western part of the city.

The application of July first nineteen hundred and five states in part as follows:

"By reason of the growth in population and the largely increased consumption of water in the district which it was incorporated to supply, the said Water Company has found it necessary from time to time to enlarge its works and increase its source of supply, and for the same reasons it is now necessary to further increase its works and sources of supply—the population now supplied by said Water Company aggregating approximately sixty thousand.

"Said Water Company has not at the present time a sufficient supply of pure and wholesome water, and for the purpose of meeting the increased demands upon it for supply of water, it duly and legally appropriated the waters of Salt Lick Run in East Taylor and Jackson townships, Cambria county, Pennsylvania, on the fourteenth day of September, 1904, and located its reservoir on said run in East Taylor Township. On the nineteenth day of September, 1904, said water Company filed its bonds in the Court of Common Pleas of Cambria county in condemnation proceedings of said stream of water and the riparian owners affected thereby, which bonds were duly approved by the Court and certain work in the way of surveys and the sinking of test pits on said stream at the site of the proposed reservoir has been prosecuted by said Water Company, and the said Water Company now wishes to actively begin the construction of said reservoir and its works on Salt Lick Run.

"Salt Lick Run is a mountain stream whose watershed is quite sparsely populated and whose waters are exceptionally pure, wholesome and palatable."

On Salt Lick Run, one quarter of a mile above its junction with the Little Conemaugh River, about six miles northeast of Johnstown, is a small intake dam in East Taylor township just above the village of Mineral Point. Above the intake the run has a drainage area of eleven and four-tenths square miles in East Taylor, Jackson, Cambria and Croyle townships. From a detailed sanitary inspection made by the Department in nineteen hundred and seven, it appears that there are in this drainage area thirty-six farmsteads and a population of one hundred and ninety-eight, and about four hundred domestic animals. Many verbal orders were given and four written orders, issued by the Commissioner of Health, were served for the abatement of menaces to the purity of the streams. About half the drainage area is under cultivation, the upper half near the sources of the streams, and here are located practically all of the habitations for the most part close to the sources. At least the lower two miles of the course of the run is through uninhabited, wooded ravines. The surface formation is sandstone and shale and very hilly.

Lumbering operations will probably be carried on on the drainage area for several years to come, although the saw mill to which most of the lumber is taken is below the intake. One of the Argyle Mines of Coulter and Huff, Greensburg, Pennsylvania, has four openings on the shed near the head of Custer Run. Drainage flowing from three of these and pumped from the fourth is

conducted in a cemented, terra cotta pipe line about two miles in length and discharged several hundred feet below the intake of the water company. This arrangement was brought about through a provisional clause in the deed or lease by which the mine operators acquired their rights from the Cambria Steel Company. Under date of February fifth, nineteen hundred and seven, the President of the Johnstown Water Company petitioned the Department to investigate and take such action as the interests of the public health might demand relative to the proposed opening of a mine and building of a village on the watershed by the Pennsylvania Coal and Coke Company. These proposed operations have not proceeded further than the digging of test pits about two miles above the intake and it is not known that it is intended to proceed further in the near future. Practically the whole shed is underlain by coal. The Cambria Steel Company is reported to to own about one-third of the mineral, the Pennsylvania Coal and Coke Company probably the majority of the mineral and about one square mile of surface area.

A twenty inch pipe extends from the intake on Salt Lick to the valley of the Little Conemaugh and in this valley about six miles to the eastern part of Johnstown where it is connected with the distributing system of the eleventh ward. The Manufacturers Water Company originally used the lower part of this line to convey water from a dam on the Little Conemaugh River, but this dam has been abandoned and the connection to it is reported to have been removed.

A large impounding dam is proposed to be erected near the site of the present intake on Salt Lick Run in the near future, just when has not been determined. It is intended to extend the main from the eastern part into the heart of the city.

The application of June twenty-second, nineteen hundred and seven, stated in part as follows:

"By reason of the growth in population and the largely increased consumption of water in the district which it was incorporated to supply, the said Water Company has found it necessary from time to time to enlarge its works and increase its source of supply, and for the same reasons it is now necessary to further increase its works and sources of supply—the population now supplied by said Water Company aggregating approximately 70,000.

"Said Water Company has not, at the present time, a sufficient supply of pure and wholesome water to meet the demands of the public furnished with water by its system, and for the purpose of meeting such increased demands upon it, it did on the fifth day of November, nineteen hundred and two, duly and legally appropriate by survey and resolution seven million gallons of the water of North Fork of Ben's Creek in Conemaugh township, Somerset county, Pennsylvania, and located a reservoir on said North Fork in Conemaugh township at a point nine hundred and ninety-five feet below the entrance of Alwine's Run into said North Fork: and the said Water Company since its said appropriation has legally acquired the tract of land upon which said reservoir was located and is to be constructed; that the said Water Company has in the meantime done certain work in connection with said reservoir such as the sinking of test pits, etc., and it now wishes to actively begin the construction of said reservoir and the laying of its pipe leading from said reservoir to the City of Johnstown. (A certified copy of the resolution adopted by said Water Company November 5, 1902 and the map accompanying said resolution is hereto attached and made part hereof).

"The said North Fork of Ben's Creek is a mountain stream whose water shed is sparsely populated and whose waters are pure, wholesome and palatable."

The resolution of the Board of Directors of the Johnstown Water Company providing for appropriating seven million gallons daily of the water of said north fork of Ben's Creek estimates the quantities to be contributed by the three main branches of the stream above the intake as follows:

North Fork of Ben's Creek three million, five hundred thousand gallons daily.
Alwine Run, two million, four hundred and fifty thousand gallons daily.
Lick Run, one million and fifty thousand gallons daily.

These figures probably represent pretty closely the proportions of the total stream flow contributed by the branches.

The North Fork of Ben's Creek is in Somerset county southwest of Johnstown and beyond Mill Creek and Dalton Run. Above the site of the proposed intake which is in Conemaugh township, Somerset county, the stream has a drainage area of nine and seven-tenths square miles in Conemaugh and Jenner townships, Somerset county and Upper Yoder township, Cambria county. The surface formation is sandstone and shale. The Johnstown Water Company owns between one hundred and two hundred acres at the site of the proposed intake which is about seven thousand feet above and west of the junction of the north and south forks of Ben's Creek. Laurel Hill, a high, well defined ridge dividing Somerset and Westmoreland counties, is the northwestern boundary of the watershed.

Alwine Run, the most northern of the three branches of the streams above the intake, rises from two sources on the slope of this ridge, whence the streams flow through deep valleys, mostly wooded. On this drainage area there are six or eight farms, some on the cultivated plateaus above the valleys and some along the streams.

North Fork, the central and principal branch of the stream, rises from two sources, also in the wooded mountain side, and from these sources streams flow through the wooded valleys similar to those of Alwine Run although the area drained is considerably larger. There are six or eight farms in the drainage area.

Lick Run, the most southern of the three branches, has one source in the wooded mountain side but by far the greater part of its waters come from a cultivated area comprising the southern part of the drainage area. The course of the stream almost to the site of the proposed intake is through open, cultivated country. There are about sixteen farmsteads in this area and almost all of them are located close to small tributary runs.

The whole drainage area has a population of perhaps two hundred people. Lumbering operations will probably be continued on the shed for several years to come. A large part of the underlying mineral is said to have been bought up by mining companies. At present there are no openings and mining operations on or under the shed other than small drifts used by local residents.

The Water Company is now constructing a thirty inch main to extend from the heart of the city to the junction of the mains from the Mill Creek and Dalton Run reservoirs. It is proposed next year, to extend this thirty inch main up the valley of Ben's Creek and the North Fork of Ben's Creek to the site of the proposed intake on the latter and to erect at this site a small intake dam in order that water may be furnished during the summer of nineteen hundred and nine. Later it is proposed to erect a large impounding dam at the site of the intake.

The experience of recent years, and particularly of the summer and fall of nineteen hundred and eight has shown the necessity for augmenting Johnstown's water supply. The addition of the two proposed sources will increase the total drainage area of the streams from which the city is supplied, by sixty-five per cent., and should when the impounding dams and pipe lines have been constructed, make the total supply adequate to meet the demands of the consumption.

The drainage areas of the two proposed sources being sparsely populated, should, if properly patrolled, yield reasonably safe domestic water supplies, particularly when opportunity for sedimentation is provided by large impounding reservoirs. Until these reservoirs are in use, the patrol of these sheds should be frequent and vigilant, because if the streams should become polluted, the supply could rarely be shut off before some of the infected water had been furnished to the consumers. It is, therefore, desirable that the impounding reservoirs be constructed as soon as practicable.

The watersheds of the new sources are but little more densely populated than those of the older sources and the quality of the water furnished by the company in the past has seemingly been generally satisfactory. The city's typhoid rate has been high, but it cannot be said that this is due to the public water supply, since the disease has never developed more extensively in a district supplied from any one source than in the others. The presence, in the city, of a large, uneducated, foreign element has probably raised the typhoid rate.

JOHNSTOWN TYPHOID CASES. FROM STATE DEPARTMENT RECORDS.

December,	11	32	..
Total,	161	160	137

In September nineteen hundred and five, the Department at the request of the water company, advised with the said company concerning the operation of the water works subsequent to the discovery of the pollution of the Mill Creek source of supply by typhoid infected sewage, and took charge of cleaning up the premises where the cases of typhoid had occurred. Subsequently the Department has had sanitary inspections made of the various drainage areas from which the water company obtains its supplies and has caused the abatement of numerous nuisances along these streams. The Department intends to continue such inspections of the watersheds. The water company should continue the various stream patrols in order that permanent menaces to the quality of the water may be reported to the Department as soon as possible after their discovery.

Under date of August thirty-first, nineteen hundred and eight, a large number of citizens of the seventeenth ward of the city of Johnstown—the district known as Moxam—petitioned the Attorney General to take the necessary steps to compel the Johnstown Water Company to carry out the purposes for which it was chartered and supply the said petitioners and others with the necessary water for domestic and other purposes, stating that the said Water Company had hitherto failed, neglected and refused to furnish water to the said petitioners after having accepted pay for the same and was continuing to do so, and that although frequent promises had been made by the said company to remedy the evils complained of during the

past eight or ten years, the conditions remained the same; and stating further that the existing conditions amounted to a nuisance, due to the lack of water in toilet rooms; and stating further that the said water company had an ample supply of water in its reservoir to supply the said petitioners and all others with the necessary water at all times, but that the supply was cut off from the petitioners early in the morning of each day and remained off during the entire day.

The water company reports having recently connected the northern part of the distributing system in the seventeenth ward with one of the supply mains in the Stony Creek valley. It is expected that this arrangement and the thirty inch main being constructed in the valley and the addition of the North Fork of Ben's Creek as a source of supply will make more efficient the services furnished in the seventeenth ward and better the conditions complained of in the petition already cited. It is reported that the poor service in the past has been due entirely to the high elevation of this district and the water company does not consider itself blameworthy since the company in its contracts with individual consumers does not hold itself liable for deficiencies or failure in the supply of water, whether occasioned by shutting off water to make repairs and connections, or by any cause whatever beyond its control.

It has been determined that the proposed water works and sources of supply will not be prejudicial to the interest of the public health, and a permit is hereby issued therefor and for the supply of water to the public therefrom under the following conditions and stipulations:

FIRST. Before the proposed dams are built, detail plans thereof and of the reservoirs shall be submitted to the Commissioner of Health for approval and the same information shall be submitted with respect to the existing dams and reservoirs.

SECOND. Plans of the watersheds above each dam and reservoir of the company, showing the highways, streams and occupied estates shall be prepared and filed by the company in the office of the State Department of Health on or before March first, nineteen hundred and nine.

THIRD. The supply mains from the new sources shall be provided with adequate drainage facilities. Plans and profiles of these supply mains shall be filed in the office of the State Department of Health on or before March first, nineteen hundred and nine. Also on or before said date the water company shall file plans of its pumping station, layouts, force mains and distributing reservoirs or tanks. And at the close of each season's work the company shall file a plan in the office of the said Department of Health showing the water pipes laid during the year, together with any other information in connection therewith that may be required in order that the Commissioner of Health may be always informed of the extent of the water works system and the public use thereof.

FOURTH. The Water Company shall maintain a sanitary patrol of the water sheds and inspections at each occupied estate and at every lumber camp or other occupied property shall be made by the company at least monthly and a report made thereof and filed with the State Department of Health. The water company shall see that the proper receptacles for sewage are provided at all such occupied camps and estates and that these receptacles shall be used and properly maintained to prevent any contamination whatsoever of surface waters on the watershed. Any neglect on the part of any owner or individual to comply with sanitary regulations shall be promptly reported by the water company to the Commissioner of Health. Presence of any infectious diseases on the watershed shall also be promptly noted and reported to said Commissioner.

FIFTH. The company shall keep weekly reports of the operation of its system or systems on blank forms satisfactory to the State Department of Health and submit copies thereof for filing in said office whenever this is required.

SIXTH. If at any time, in the opinion of the Commissioner of Health, the water supply or the water works, or any part thereof, is found prejudicial to public health, then the water company shall adopt such remedial measures as the Commissioner of Health may approve or advise.

SEVENTH. The Johnstown Water Company shall not supply water from any other source other than these hereinbefore designated as its own and herein approved, except in cases of emergency fully warranting such use whereupon the company shall immediately give notice to the State Department of Health.

EIGHTH. This permit shall not be construed as approving the supply of water to the public in any territory beyond that authorized by the company's charter. If there be any question as to the right of the company under its charter to supply the public in Dale, Ferndale and Westmont boroughs, or Walnut Grove village, the Commissioner of Health will be glad to act favorably on an application for approval, after an extension of the charter rights of these territories is granted by the State Water Supply Commission.

With respect to the Morrellville and Cambria Borough Water Company, said company will be required to submit detail plans of its dam and reservoir, watershed and pumping station and that it be required to make the customary sanitary inspections monthly of watersheds, similar to recommendations hereinbefore offered to the Johnstown Water Company.

With respect to the Manufacturers Water Company, since it supplies water to the Johnstown Water Company for drinking purposes sometimes, the company will be required to submit plans of its intakes, dam and supply main.

With respect to the Cambria Steel Company's Hinckston Run supply, since this is used in emergencies as a source of supply to the Johnstown Water Company, this company will be required to file in the office of the State Department of Health plans of the dam, reservoir, watershed and supply pipe, and the company will be further required to conform to any regulations about sanitary patrol of the watershed which the State Department of Health may establish.

The city and the surrounding borough authorities will be notified that the prevalence of typhoid fever in the community is attributable to quite an extent to polluted surface springs and wells from private estates and that there is a great necessity of a vigilant inspection of these private sources of drinking water and the discontinuance of all such as are subject to contamination.

Harrisburg, Pa., November 20, 1908.

LOWER ALLEN TOWNSHIP, CUMBERLAND COUNTY.

Riverton Consolidated Water Company, Riverton Village.

This application was made by the Riverton Consolidated Water Company of the village of Riverton, Lower Allen township, Cumberland county, and is for approval of extensions of water works and for permission to increase its source of supply.

It appears that opposite the city of Harrisburg on the west bank of the Susquehanna river there was formerly a settlement in the township of Lower Allen known as Riverton. Now there are three boroughs in the district.

Recently Wormleysburg borough has been incorporated out of the township of East Pennsboro. It has a population of about six hundred and its territory extends along the river from just north of the People's Bridge approach, northerly about a half mile and back from the river to the low grade freight line of the Pennsylvania Railroad. Some distance beyond this borough and north of it is the village of West Fairview in East Pennsboro township, and north of West Fairview is the village of Enola in the same township. The latter place has its own independent system of water works.

Crossing the Susquehanna river a few hundred feet below the People's Bridge are the tracks of the Cumberland Valley Railroad and down stream about a quarter of a mile the tracks of the Philadelphia and Reading Railway are carried over the river Between these parallel lines from the west bank of the river westerly for a distance of about a mile is the village formerly called Riverton but now incorporated into the borough of Lemoyne and containing one thousand inhabitants.

Northwest of Lemoyne on the rising ground is the borough of Camp Hill, rapidly growing and containing a present population of about seven hundred. It was incorporated out of East Pennsboro township. Lemoyne was incorporated out of Lower Allen township.

It appears that the Riverton Consolidated Water Company was formed by merger and consolidation, by and between the Riverton Water Company, the Susquehanna Water Supply Company, the Allen Spring Water Company, the East Pennsboro Water Company, the Fairview Township Water Company and the Mountain Water Company, of New Cumberland, notice of which agreement was filed in the office of the Secretary of the Commonwealth on February seventeenth, nineteen hundred and four.

The Riverton Water Company was incorporated under the laws of the State on June second, eighteen hundred and ninety-two, for the purpose of supplying water to the public at Riverton, Cumberland county. It was sold, under the Act of April eighth, eighteen hundred and sixty-one, and the supplement thereto, (which Act concerns the sale of railroads, canals, turnpikes, bridges and plank roads) on account of a mortgage by deed dated November nineteenth, nineteen hundred and three. Later the Riverton Water Company filed a certificate of re-organization in accordance with the law, said certificate being filed in the office of the Secretary of the Commonwealth under date of December twenty-ninth, nineteen hundred and three.

The Susquehanna Water Supply Company was chartered on December sixth, eighteen hundred and ninety-seven, for the purpose of supplying water to the borough of Camp Hill, Cumberland county, Pennsylvania.

The Allen Spring Water Company received its charter under date of December eleventh, nineteen hundred and one, for the purpose of supplying water to the public in the township of Lower Allen, Cumberland county, Pennsylvania, except all such portions of said township as may be covered by the Riverton Water Company.

The East Pennsboro Water Company was chartered December ninth, nineteen hundred and one, for the purpose of supplying water to the public in the township of East Pennsboro, Cumberland county, Pennsylvania, except all such portions of said township as may be covered by the Riverton Water Company.

The Fairview Township Water Company has a charter dated December thirty-first, nineteen hundred and three, for the purpose of supplying and furnishing water to the public in the township of Fairview, York county, Pennsylvania.

All of these companies had the same treasurer when they were incorporated and it is evident that the project was to ultimately effect a consolidation.

The Mountain Water Company of New Cumberland was chartered February twentieth, eighteen hundred and ninety-six for the purpose of supplying water to the public in New Cumberland.

It further appears that there is a concern known as the Shiremanstown Water Company. Shiremanstown is a borough of about seven hundred population, located on the line of the Cumberland Valley Railroad about two miles beyond Camp Hill. It lies partly within Lower Allen township. The Shiremanstown Water Company was chartered on August thirty-first, nineteen hundred and three, for the purpose of supplying water to the public in the borough of Shiremanstown. This corporation is identified with the Riverton Consolidated Water Company and has made application for permission to obtain its source of supply from the Riverton Consolidated Water Company.

There are a number of other companies which have been chartered at different times to supply some of the districts, now being supplied by the Riverton Consolidated Water Company, whose rights have lapsed because of non-use. These companies were the New Cumberland Water Company, chartered on April fifteenth, eighteen hundred and ninety-five, to supply water to the public in the borough of New Cumberland; the Camp Hill Spring Water Company, chartered on October nineteenth, eighteen hundred and ninety-seven, to supply water to the borough of Camp Hill in East Pennsboro township, Cumberland county; the Camp Hill Water Company, chartered April fifteenth, eighteen hundred and ninety-five to supply water to the public at the borough of Camp Hill, in the township of East Pennsboro, Cumberland county, and the Riverside Water Company, chartered February sixth, nineteen hundred and three, for the purpose of supplying water to the public in and throughout the township of East Pennsboro, Cumberland county.

On October twenty-third, eighteen hundred and ninety-five, an ordinance was passed by the council of Camp Hill granting a franchise to the Cumberland Water Company, which company was chartered April fifteenth, eighteen hundred and ninety-five, for the purpose of supplying water to the public at the village of Boiling Springs and the township of South Middleton, Cumberland county. This company was afterwards sold to the Carlisle Water Company, the notice of sale appearing on the books of the office of the Secretary of the Commonwealth, under date of August thirty-first, eighteen hundred and ninety-six. This company never did any work in the borough, probably for the reason that their charter rights would not permit them to enter said borough.

The Riverton Water Company was then granted a franchise, on October twenty-second, eighteen hundred and ninety-seven, to lay pipes in the borough of Camp Hill. It would appear from an inspection of their charter rights that they could not legally supply water to said borough. Camp Hill, however, was a borough in eighteen hundred and eighty-five, prior to the incorporation of the Riverton Water Company. Therefore, the latter's charter territory does not include Camp Hill borough. Less than two months after October twenty-second, nineteen hundred and seven, when the Camp Hill authorities undertook to give rights beyond the charter to the Riverton Water Company, a charter was obtained by the Susquehanna Water Supply Company, before mentioned, to supply Camp Hill borough.

Thus it may be seen that the Riverton Consolidated Water Company has a right by virtue of the merger and consolidation above described to supply water to the public in Wormleysburg, Lemoyne, Camp Hill and New Cumberland boroughs, in East Pennsboro and Lower Allen townships, Cumberland county, and also in Fairview township, York county.

New Cumberland is a borough of about eighteen hundred population and including the suburbs of Elkwood and Rosemont, there are about twenty-five hundred people living in the community. The town is on the river at the mouth of the Yellow Breeches Creek, on the opposite side of which is Fairview township in York county.

The charter territory of the water company thus extends from Perry county on the north into York county on the south and along the Susquehanna river opposite Harrisburg. It contains a population of about twelve thousand people. Most of the citizens are employed in Harrisburg and at the mills at Steelton and also by the railroad companies. There is also considerable farming population in the district.

In the northern part the geological formation is shale, in the central limestone and in the southern part Huronian Rocks. The country is rolling in the north, flat through the centre and there are high hills in the south.

There are two large streams which pass through the district into the Susquehanna river. They are the Conodoguinet and Yellow Breeches Creeks. The former rises in Franklin county and flows easterly passing north of and near the borough of Carlisle and empties into the Susquehanna river, opposite the city of Harrisburg. This stream has many tributaries; those coming from the south rising in springs in the limestone formation and those from the north draining slate and sandstone formation. It has a water shed area of four hundred and forty square miles and drains six boroughs, having a total population of about nineteen thousand. The territory through which this stream passes is agricultural and most of it is low, undulating land, thereby causing the course of the stream to be winding and the flow sluggish.

Yellow Breeches Creek is the dividing line between Upper and Lower Allen townships in Cumberland county and Fairview and Monaghan townships in York county. The stream rises in South Mountain in the southwestern part of Cumberland county and flows in a general northeasterly direction for a distance of some thirty-two miles in a straight line to the river at New Cumberland. The area so drained comprises about two hundred and thirty-eight square miles, about one-third of it being mountainous. The northern portion of the water shed is in the limestone formation, while the southern part is underlaid with sandstone and Huronian rocks. About one-half of the watershed is in limestone and the other half in sandstone formation, the creek bed being entirely on the limestone side. The water therefore, is fairly hard in summer when about half the flow is ground water from the limestone country.

Distributed for a distance of fifty miles along the banks of the Yellow Breeches Creek there are two boroughs and eighteen villages and settlements, comprising a total population of about sixty-five hundred, which is fifty-three per cent. of the entire population of the water shed. The balance of the people living thereon are widely distributed over a drainage area averaging twenty-five individuals per square mile.

There are two pleasure resorts along this stream, namely: Mt. Holly and Williams' Grove, seventeen and twenty-seven miles above the mouth, respectively. The former receives thousands of visitors during the summer months by way of the trolley system, while the latter is a camping ground where people pitch tents and where, during the week of the annual convention of the State Grange Association, from five to fifteen thousand people congregate in one day.

There are two sources of supply used by the Riverton Consolidated Water Company, the first being from the hills in Fairview township, York county and the second from the Susquehanna river. The hill water is furnished to some of the houses along the pipe line in Fairview township to New Cumberland borough and vicinity and to Lemoyne and vicinity. The river water is furnished to Wormleysburg, Camp Hill and villages in the vicinity in East Pennsboro.

The supply from the hills in Fairview township comes from a small run on the old Haldeman estate and from a run distant about a mile south. Each stream has a reservoir on it, the first being known as the old reservoir and the latter being known as the new reservoir. They were both built by the Mountain Water Company.

The old reservoir, built in eighteen hundred and ninety-six, consists of an earth embankment thrown across a gulley. The dam is one hundred and twenty-five feet long and it backs the water up to an average depth of about ten feet, the reservoir being about three hundred feet long. There is a small spillway four feet wide and eighteen inches deep in one corner of the dam. There is a twelve inch blow-off pipe and a six inch blow-off pipe extending through the embankment and having gate valves on them in the reservoir. The gulley on the sides was excavated and retaining walls built and these extend back for about one third of the distance on the sides, the remaining portions being earth slopes. On the east side there is an old unused road along the retaining wall. On the west side there is a ditch designed to carry the run-off from the water shed to below the dam.

The drainage area of the reservoir is about one-quarter of a square mile. It is mostly wooded, but there are a few pasturage fields on it and one residence. A small proportion of the land only is owned by the water company. No plans of the company's holdings have been submitted.

After a heavy rain the water in the reservoir becomes turbid. A man living at the foot of the hill is employed by the company to divert from the reservoir the first run-off after a heavy rain. The run is dyked above the basin to the by-pass around the reservoir and the man cuts the water off by means of a box sluice way and plants provided in the run for by-pass purposes.

The reservoir holds one million gallons, so it is reported. It is elevated about one hundred and eighty feet above New Cumberland borough and is enclosed in a fence to keep out the public. The flow of the run into the reservoir has been measured as two hundred and fifty thousand gallons per twenty-four hours in the spring of the year.

From the reservoir there is a six inch gravity supply main extending northerly across private property and under Yellow Breeches Creek to New Cumberland borough, two miles distant.

The new reservoir was built in nineteen hundred and two. The dam is of earth construction, one hundred and fifty feet long, and the water is back-flooded one hundred feet and its maximum depth is fifteen feet. This small basin operates as not much more than an intake. The water company owns and controls the land adjacent to the reservoir and the greater part of the headwaters of the stream. The watershed comprises thirty-five hundredths of a square mile, about two-thirds of it being open field and the remainder wooded land.

There are four habitations above the reservoir. Three of them are on the land owned by the water company. The properties are rented and under conditions precluding the cultivation of land near the run and requiring precautions to be taken to obviate sewage pollutions. Intervening between the company's property on the watershed and the reservoir there is a strip of land about a half mile wide owned by private individuals, on which there is one farm. The public road passes at right angles to the stream across the watershed through this portion. Above the road there is a swampy ground and ducks from the barnyard nearby paddle in the

waters of the stream. The barn is not over two hundred feet distant. Below the road the private land is pasturage, but the water company owns the stream rights and has laid an eight inch terra cotta pipe from the upper side of the road to near the reservoir. The object of this improvement was to collect the water where it was not subject to much pollution and convey the water from the pipe into the reservoir. For some reason, however, this improvement has not been completed, so that now all the drainage from the road and the barnyard and the entire watershed gets into the reservoir except during extraordinary floods, when, by an arrangement built for the purpose at the uper end of the basin, the water is diverted and sent around below the dam. So ordinary storms and muddy waters all get into this basin and, the capacity being small, much sediment is carried on into the gravity supply main. The reservoir is elevated eight feet above reservoir number one. It is fenced in and the supply pipe from it to the town is six inches in diameter. No plans of the dam or reservoir have been submitted to the Department and the means of collecting water through the intake are not known in detail.

The six inch pipe follows down the valley of the run, largely across private property and paralleling the public road, crossing the line of the six inch pipe from reservoir number one and extending under the Yellow Breeches Creek into New Cumberland borough via Rosemont, joining, or supposed to join, at the crossing of Gerry and Third streets. There is a blow-off on the pipe line from number two reservoir.

From New Cumberland an eight inch supply main extends northerly in the public road a distance of about two miles to Lemoyne borough, supplying on its way Riverton in Upper Allen township and also the Philadelphia & Reading Railway tank in said township. Off this line there are branches in Lemoyne borough. One special branch is six inches in diameter and extends up Hummel avenue, reducing to four inches where it extends out into the township to White Hill village. At the crossing of Cumberland street it connects with a pipe in Camp Hill borough. This point is five and one-third miles from the reservoirs.

The Susquehanna River supply is taken from the river at Wormsleysburg less than two hundred feet above the People's bridge across the river from the end of Walnut street in the city of Harrisburg. At this point there is an old pumping station, about thirty-five feet square, one story and constructed of brick, having in it two eighty horse-power boilers and a Worthington compound double acting pump, fourteen by twenty by twelve by fifteen inches. It is reported by the pump man that the pump is operated every day and then only for a period of about five hours.

A twelve inch intake extending about one hundred and fifty feet out into the low water in the river and having on its end a cone-shaped copper screen delivers the water to a pump well about eight feet square, which is divided into two compartments by a half inch mesh screen vertical and extending eight feet from the bottom, the total depth being fifteen feet. From the pump well there is a twelve inch suction line to the pump. During floods the pump is submerged and cannot be operated and during excessive freshets the fires in the boilers are put out.

The pumping engine is a horizontal duplex compound one, having a rated capacity of about one and a half million gallons, but it is old and out of repair, leaks badly and its efficiency is cut down to about one million gallons per twenty-four hours and, so far as can be ascertained, this is the rate at which it is operated. At present the pump is run (as stated above) five hours out of every twenty-four and it raises between two hundred thousand and two hundred and twenty-five thousand gallons of water into a cement lined reservoir on Fort Washington hill nearby in East Pennsboro township. The rising main is ten inches in diameter.

The distributing reservoir is about eighty feet square at the top, the sides sloping so that the flow line is about seventy-five feet square. The water has a depth of nine feet, equal to a capacity of two hundred and forty thousand gallons. The force main enters the reservoir in a vertical position, the water flowing over the top and falling three feet to the level in the basin. There is an overflow through to a gulley on the side hill and also a drainage pipe, but this is plugged tight. The reservoir is made by excavation with a heavy earth embankment and surrounded by a fence seven feet high. The water level is two hundred and fifteen feet above the pumping station and eight feet above the new reservoir in Fairview township, York county, and distant therefrom four and four-tenths miles.

The river water is all pumped into the Fort Washington reservoir. From it an eight inch gravity supply main is laid to Lemoyne and a four inch pipe line is laid to Wormleysburg. The former line extends into Lemoyne and connects with the mountain water line from New Cumberland and by means of an arrangement of valves on either side of Lemoyne this river water can be supplied to New Cumberland, Lemoyne and White Hill and to Camp Hill, districts which nominally should get the hill water.

A pipe is taken off of the the eight inch line from Fort Washington reservoir and extends up the Mechanicsburg pike to Camp Hill borough. This line is six inches in diameter and it has a connection with the four inch pipe from the mountain water supply at Cumberland street hereinbefore mentioned. From this point a four inch line carries the water to the western part of Camp Hill borough, two and six-tenths miles from Fort Washington reservoir and one hundred and six feet below it.

The four inch line which comes down from the reservoir to Wormleysburg cannot receive mountain water.

The pumping station, Fort Washington reservoir and connecting pipes were the original works of the Riverton Water Company.

In the districts supplied by the Riverton Consolidated Water Company there has been much complaint about the quality of the water and the inefficiency of the service. Formerly New Cumberland had ample water supplied by the Mountain Water Company, but since the consolidation and the extension of the district furnished by this mountain water complaints about scarcity of the supply have arisen.

On January seventh, nineteen hundred and seven, during the typhoid fever epidemic at Scranton, the Commissioner of Health advised the Riverton Consolidated Water Company as follows:

"Gentlemen:

"I fear that there is an unusual amount of typhoid fever infection in the Susquehanna river by reason of the epidemic of the disease now prevalent in the city of Scranton. While I have issued instructions to the mayor of that city to disinfect all discharges from typhoid fever patients before said discharges leave the premises, yet I have grave doubts that said instructions are generally observed with reference to convalescents, and consequently conclude that the Susquehanna river water, into which the sewers of the city of Scranton empty, is an unusually dangerous source of supply of water to the public at this time. It becomes my duty to warn you not to furnish this supply to your consumers unless it be first adequately filtered, otherwise you are to notify the public to boil the water for a period of thirty (30) minutes before the same is used for drinking or culinary purposes.

"Yours very truly,

"SAMUEL G. DIXON.

It apepars that no action was taken by the company in reference to this matter, so far as the Department is informed.

On January nineteenth, nineteen hundred and seven, the Commissioner of Health notified the president of the water company that the river source contained sewage and that pure water must be furnished the consumers. The communication was as follows:

"Mr. Patricio Russ,
"Pres. Riverton Consolidated Water Company,
"Harrisburg, Pa.

"Dear Sir:

"Two samples of water taken from the well at your pumping station, at Wormleysburg, reveal the presence of the b. coli communnis. The presence of these organisms is taken as an evidence of sewage pollution, and I beg to inform you that some action will be necessary on the part of your company to furnish water free from sewage pollution.

"Yours very truly,
"SAMUEL G. DIXON,
"Commissioner of Health."

No action was taken concerning this communication.

Still further, as showing the derelictness of the company in discharging the obligations of its charter, it appears that on December eleventh, nineteen hundred and six, the State Department of Health sent the following communication to the secretary of the Riverton Consolidated Water Company:

"This is to call your attention to the matter of filing report and plans of your water works system, with respect to which a correspondence passed between us a number of weeks ago, at which time you promised to file the said report and plans in the immediate future."

On July sixth, nineteen hundred and seven, the Commissioner of Health placed in the hands of an attorney the matter of proceeding against the Riverton Consolidated Water Company. The communication of Frank M. Eastman, Department counsel, to the water company is given in full below:

"Harrisburg, Pa., July 25th, 1907.

"A Grant Richwine, Esq.,
"Secy. Riverton Consolidated Water Company,
"Lemoyne, Pa.

"Dear Sir:

"I am in receipt of your letter of July 24th and note its contents.

"Section 3 of the Act of April 22, 1905, provides that no private corporation shall construct water works for the supply of water to the public within the State, *or extend* the same, without a written permit to be obtained from the Commissioner of Health. That a permit is necessary for an extension not necessarily involving an additional source of supply appears from the penalty clause of said section;

"'The penalty for failure to file copies of plans, surveys and descriptions of existing water works within the time hereinbefore fixed, and for the construction of extension of water-works, *or the use of an additional source of supply* without a permit from the Commissioner of Health shall be $500.00, etc.'

"In this clause, as you will notice, the construction or extension of water works is contradistinguished from the use of an additional source of supply.

"The report of your system of water works filed with the Department in April, 1906, was incomplete in many respects, but it was tentatively accepted with the understanding that the Department would call upon your company for such further data as might be required. Considering the status of the company as established as of the data of said filing, you have since made numerous extensions for which you should have had permits from the Department, and failing to apply and receive the same your company has incurred the penalty provided for in the Act of 1905.

"I send you in the same mail with this blank on which to make application for a permit to make the extensions which you have already made, and such further ones as you may now have in contemplation. If you will promptly fill this up and return it to me forthwith, and otherwise comply with the requirements of the Department in this regard, I shall not proceed against the company for the penalty already incurred; otherwise I shall.

"Your attention is called to the fact that some time last fall the Department advised you that typhoid germs existed in the water supplied by you to the public, and you were instructed to take such action as might be necessary to supply the public with pure water. Nothing appears to have been done by you in this regard, and the fact that your water supply is impure is evidenced by the fact that typhoid is or has recently been epidemic in the borough of Camp Hill which you supply with water.

Unless immediate steps are taken by your company to purify its water supply, I shall on behalf of the Commissioner of Health institute such legal proceedings against your company as may seem advisable. I wish to be advised what your intentions are in this regard at your earliest convenience.

Very truly yours,

(Signed) FRANK M. EASTMAN,

"Counsel, Health Department."

In response to this letter the application of August twelfth, nineteen hundred and seven, was made for approval of the extensions to pipe lines already made.

Also in response to this communication the water company did, on May twentieth, nineteen hundred and eight, submit the application herein under consideration for increased source of supply. However, the plans accompanying this application, which plans were absolutely necessary to consider the proposition were not submitted in the Department until June twenty-ninth, nineteen hundred and eight.

During the summer of nineteen hundred and seven the Department made a series of tests of waters at various places in the districts of the Riverton Consolidated Water Company. The results of the tests of samples taken from the Philadelphia and Reading Railway tank at Lemoyne, the water coming from the mountain supply, showed no pollution. The water collected from the tank at the Cumberland Valley Railroad, west of Lemoyne, which tank was being supplied from the river pumping station when the samples were taken, this being accomplished by opening the valve at Cumberland street in Camp Hill borough and closing the one at the Cumberland Valley tracks, showed some pollution. About twenty families at White Hill were being furnished with this supply. At some other times these families received mountain water. No notice of change in the water supply was given by the company.

The samples of water collected at the well at the pumping station and also samples of water collected at the Fort Washington reservoir showed sewage pollution.

In the water company's district the prevailing methods of sewage disposal in connection with private sources of drinking water has a bearing on sickness from water borne diseases.

In New Cumberland borough, incorporated in eighteen hundred and eighty-three there are several public sewers leading to the river and to the Yellow Breeches Creek, but most of the inhabitants use the old time privy vault. There are a number of dug wells and a few drilled wells located on private properties and about twenty-five roof water cisterns. The town has been contemplating a sewer system. The sub-soil is mostly shale.

In Camp Hill borough, incorporated in eighteen hundred and eighty-five, there are no public sewers. The structure is limestone and sewage is disposed of into holes sunk therein. The method is not entirely satisfactory and some discussion has been had about establishing a sewer system. There are fourteen drilled wells reported as being used as sources of domestic supply on private properties. There was an outbreak of typhoid in Camp Hill in nineteen hundred and seven and the disease was prevalent in years prior thereto. The infection was traced by a Department officer to the Straub well, near the corner of Main street and Park avenue. It was thoroughly cleaned out and disinfected.

In Lemoyne incorporated three years ago, the method of disposal of household wastes is into sink holes drilled in limestone rock. There are a few private drilled wells in the village. Some typhoid fever occurs annually, but it has not been traced to any specific infection.

In Wormleysburg, which was incorporated into a borough during the current year, there are about one hundred and fifty houses, many of which have roof cisterns. The majority of the properties have dug wells sunk into the sand and gravel formation, from which water is drawn for domestic purposes; there are some drilled wells also. There are a few percolating cesspools and some of the old dug wells

are used as receptacles for household wastes. There has been typhoid fever in the settlement, but records thereof were not kept. Well water pollution has been suspected. From some of the dwellings located along the river front there are individual sewers leading to the river and from dwellings back from the river there are also sewers to the stream. Twenty-three sewers of this kind were found on inspection on August fourteenth, to be discharging into the river immediately above the water company's intake and connected therewith are fifty houses. Two of these sewers were laid by the township of East Pennsboro, so it is reported. To one of these sewers fourteen houses are said to be connected, for which connection no permission was issued. To the other public sewer there are seven dwellings connected, the owners of which in each instance paid a tappage fee. These pipes take storm water as well as sewage. The former public sewer is ten inches in diameter and empties near the top of the river bank. The latter is twenty inches in diameter and empties about two-thirds of the way down the river bank. The private sewers discharge at the water's edge or part way up the bank. Complaint has been registered in the State Department of Health about a nuisance arising from the depositing of sewage anywhere along the shores of the river. Local garbage from the settlement is thrown over the embankment and the conditions in this respect are filthy all along the shores above the water intake. One of the nearest sewers to the intake is from Hotel Navarre, two hundred feet distant; the furthest private sewer in the borough is about a mile distant; the majority of them are within a half mile. Named in order up stream, the owners of the sewers are as follows:

No.	Location.	Size.	Ownership.
1.	50 ft. above intake,	8 inch,	Amos Snyder.
2.	75 ft. above intake,	8 inch,	Amos Snyder.
3.	150 ft. above intake,	4 inch,	A. B. Potts,
4.	200 ft. above intake,	Several outlets.	Hotel Navarre (Shamokin Brewing Co.)
5.	250 ft. above intake,	12 inch,	P. M. Heiser.
6.	Near Poplar St.,	10 inch,	Unknown.
7.	Poplar St.,	10 inch,	D. S. Brown (7 houses).
8.	250 ft. above Poplar St.,	6 inch,	Abner Yetter.
9.	300 ft. above Poplar St.,	10 inch,	A. J. Wright (3 houses and slaughter house).
10.	350 ft. above Poplar St.,	?	Willard Black.
11.	375 ft. above Poplar St.,	?	George Chambers.
12.	Market Street,	20 inch,	Township sewer.
13.	50 ft. above Market St.,	6 inch,	John Bixler.
14.	100 ft. above Market St.,	4 inch,	John Bixler.
15.	200 ft. above Market St.,	6 inch,	P. C. Coble.
16.	Locust Street,	10 inch,	Township sewer (11 houses).
17.	250 ft. above Locust St.,	?	A. J. Wright.
18.	275 ft. above Locust St.,	?	J. D. Hipple.
19.	3,000 ft. (or over) above intake,	?	Mr. Reichert.
20.	3,000 ft. (or over) above intake,	?	Mr. Fairbright.
21.	3,000 ft. (or over) above intake,	?	Mr. Wambaugh.
22.	3,000 ft. (or over) above intake,	8 inch,	Mr. Baum.
23.	3,000 ft. (or over) above intake,	8 inch,	Samuel Weidman.

The inhabitants of West Fairview village, located above Wormleysburg, use individual wells and cisterns for water supply. There are no public drains in the town.

In the village of Enola the water is supplied by the Dauphin Consolidated Water Supply Company. There is a system of public sewers and sewage disposal works owned by the Enola Sewerage Company.

Besides asking approval of the lines already laid since nineteen hundred and five, the petitioners ask approval of plans to build a new reservoir immediately above the old reservoir in Fairview township. The said new reservoir is to hold about thirty million gallons of water. It is proposed to lay a sixteen inch pipe line from this basin to the pipe in front of the Valley Traction office in Lower Allen township, near Lemoyne station, and to run an eight inch line from the square in Lemoyne to connect with this sixteen inch main. The new eight inch line is to pass directly west on Hummel avenue, Lemoyne, out through White Hill and connect with the pipe line of the Shiremanstown Water Company at Shiremanstown borough line.

The proposed reservoir will consist of an earthen dam built across a natural valley wherein the water will be impounded. It will have a rubble concrete core wall backed by stones and other heavy material and have a base of puddle material laid in six inch layers. The dam will be fifteen feet across the top and about fifty-two feet high. Its length across the top will be somewhere in the neighborhood of four hundred feet. There will be a waste weir twenty-five feet wide cut out of rock, which will reduce to ten feet in width before it discharges into the present reser-

voir. There will be a twenty inch cast iron pipe laid under the dam and it will have a screen over the inlet. At the end of the pipe at the top of the outer embankment of the dam will be a valve house in which will be located the valve of this pipe. This outlet pipe from the reservoir will discharge either into the present reservoir or will be by-passed around it to the sixteen inch pipe leading to town.

The water shed above the proposed reservoir is about one quarter of a square mile in area. At the present time the run is nearly dry. The yield from a water shed like the one in question, with the highest development of storage facilities feasible, does not average, in America, five hundred thousand gallons per square mile daily, taking into account a series of dry years. In extremely springy water sheds, where the yield is far above the normal and the springs never run dry, sometimes with adequate storage the development is equivalent to a yield of seven hundred and fifty thousand gallons per square mile during a series of dry years. The Department has not enough local information for the basis of a reliable conclusion as to what may be expected from the Haldeman reservoir proposed, other than general deductions. The engineer who designed the new reservoir estimates that the available yield when developed will not be more than three hundred thousand gallons, nor less than one hundred and fifty thousand gallons per square mile per twenty-four hours throughout a series of dry years. Said engineer, in recommending that a source equivalent to one million gallons capacity per twenty-four hours be ultimately planned for, suggested the obtaining of the additional supply from the Yellow Breeches creek at New Cumberland. Six hundred thousand gallons of the million gallon supply, he estimates, will be needed for the Lemoyne, Camp Hill and Wormleysburg districts and vicinity. Shiremanstown will need one hundred and twenty-five gallons daily, so it is reported.

The Fort Washington reservoir is to be retained as a storage and into it water will be fed from the Haldeman reservoir at night-time. It is understood that the Company's intention is to abandon the river pumping station.

The Haldeman reservoir watershed is too small to warrant expenditures for the new dam as proposed. The quantity and quality of water would not have a comparative value sufficient to render the source a desirable one for the extensive district of the Riverton Consolidated Water Company.

With a limited district, possibly for New Cumberland borough for the present, Haldeman reservoir source as it is contemplated might prove feasible from every standpoint. The territory opposite the city of Harrisburg is bound, in all probability, to witness a very large and rapid growth. One of the conditions precedent to the sustaining of an increased population is an adequate supply of pure water. Should a Greater Harrisburg ultimately take in the settlements on the west bank, filtered river water would undoubtedly be supplied to the inhabitants there. The best expert advice which the city of Harrisburg and the borough of Steelton could command reported adversely on any other source of public supply than the Susquehanna River, filtered. The Yellow Breeches Creek water is unsuitable to use without filtration. The Commissioner of Health has already stipulated that the Mechanicsburg Gas and Water Company, whose proposed new intake is to be at the Yellow Breeches Creek, shall filter the water. The Creek water is not only subject to sewage pollution, but it is extremely hard in quality and not as desirable for domestic purposes as the river water. The latter is also to be preferred over the waters of the Conedoguinet Creek. The Riverton Consolidated Water Company's expert has concluded in his report that if the company must resort to steam pumping in place of water power to raise the Yellow Breeches Creek water into the district, then it would be much better for the Riverton Consolidated Water Company, in his opinion, to do such pumping from the river and filter the water.

The Fort Washington reservoir is well located centrally for a distributing point. It is possible to place the filter on the hill and to have the filtrate flow by gravity into this reservoir.

The plans as they now stand, with the present river pumping station abandoned, would not in the opinion of the State Department of Health afford an abundant supply of pure water, and, therefore, this would be prejudicial to public health because it would force the inhabitants to resort to polluted springs and wells in the territory.

Furthermore, the river water cannot be used without prejudice to the public health unless the water is filtered. Nevertheless, this source of supply must continue, as it is now, to be the major one for the district of the Riverton Consolidated Water Company, unless the company obtain some other source of adequate supply.

It has been determined that the proposed Haldeman reservoir and a system of distributing pipes to deliver the water therefrom to New Cumberland, Lemoyne, Camp Hill and vicinity will not be prejudicial to public health under certain conditions and the same is herein and hereby approved under the following conditions and stipulations:

FIRST: That this source of supply shall be preserved and conserved and used primarily for the borough of New Cumberland and adjacent settlements, provided that when the Haldeman reservoir is full and overflowing the surplus water may be delivered into the distributing districts of the Riverton Consolidated Water Company lying beyond New Cumberland and its immediate vicinity.

SECOND: The Boyer reservoir, or reservoir number two, shall be cleaned out within two weeks from the date of this permit, the company shall complete its contemplated improvement of diverting the polluted water from the farm house, barn and property near the public highway and from the pasturage fields immediately above the reservoir to the by-pass leading around the reservoir below the dam on or before the said two weeks, and it shall provide, or cause to be provided, at all occupied properties on the watershed sufficient and suitable receptacles for all sewage and shall see to it that these receptacles are used and that the content is removed at stated periods and deposited off the watershed in some sanitary manner, and it shall forthwith remove every source of pollution on the entire watershed above the reservoir, or report promptly its inabillity to remove such pollutions to the Commissioner of Health, who will thereupon without delay take action in the premises. This work shall not be delayed. Now that the stream is dry, the time is opportune for the improvements.

THIRD: On or before November first, nineteen hundred and eight, the company shall, from actual survey, furnish a plan and elevation of the existing reservoirs, dams and appurtenances and a plan of the water sheds of the Boyer and Haldeman reservoirs showing thereon all occupied estates and highways and sources of pollution, and thereafter, so long as these watersheds shall be used as a source of supply by said company, the company shall have a monthly inspection made of every occupied estate and report the sanitary condition thereof and the existence of any menace on the watershed forthwith to the Commissioner of Health.

FOURTH: The Boyer reservoir shall be used primarily, together with the Haldeman reservoir water, for the supply of the borough of New Cumberland and immediate vicinity. Any surplus water therefrom may, as in the case of the Haldeman reservoir, be delivered into the distributing pipe system of the districts beyond New Cumberland and immediate vicinity.

FIFTH: The pipe system in New Cumberland and vicinity shall be so arranged or re-arranged that water from the Haldeman and Boyer reservoirs cannot be furnished to Lemoyne and other districts of the water company beyond New Cumberland and immediate vicinity, except at one point and here on this pipe there shall be placed a valve and the company shall keep an accurate record of this valve's operation and file sworn copies of said record in the office of the Commissioner of Health monthly. Within ten weeks from the date of this permit a certified plan of the location of this valve and the pipe arrangement in connection therewith shall be filed in the office of the Commissioner of Health.

SIXTH: On or before November first, nineteen hundred and eight, the company shall have improved its distributing system of pipes in New Cumberland borough by eliminating certain dead ends in pipe lines where the quality of water has been inferior. These dead ends shall be connected up so that the water may have a circulation in the street pipes and the entire system shall be very thoroughly flushed and cleaned out to the satisfaction of the Commissioner of Health.

SEVENTH: The company shall provide ample blow-offs and facilities whereby the reservoirs and the pipe system may be completely and readily drained and flushed and this shall be done during the current season, and a report of these improvements shall be made to the Commissioner of Health on or before the close of the year. The drainage facilities of the proposed dam are not now ample and shall be increased in capacity, provided the dam be built.

EIGHTH: The Department of Health does not advise at this time the construction of the new reservoir. In its opinion, by far the best plan would be to obtain the entire water supply for all but New Cumberland from some approved point in the Susquehanna River and to filter the water and supply it from the Fort Washington reservoir to the entire water works district. Improvements in the distributing system of pipes according to this plan would be permanently made. The main supply pipes could be laid down with the assurance of their being able to meet the demands of the present and future consumption for the territory along the west bank of the river in Cumberland County and now comprised within the charter territory of the Riverton Consolidated Water Company.

NINTH: Since the Riverton Consolidated Water Company is now supplying and must continue for some time to supply raw water to a part of its water district, it is expressly stipulated that the company shall forthwith notify its consumers and the public by several publications in the daily newspapers that the source of supply taken from the river is subject to sewage pollution and that safety to public health requires that all such water so supplied and used for domestic purposes shall be boiled for thirty minutes.

TENTH: The Riverton Consolidated Water Company shall, on or before November first, nineteen hundred and eight, submit plans and specifications to the Commissioner of Health for approval for a water purification plant for the treatment and purification of all river water supplied by the company to its consumers. These plans shall comprise the adaptation of modern methods of water treatment, and they will be approved, modified or amended by the Commissioner of Health and as so modified, amended or approved they shall be built. The company shall begin construction of the works according to the plans approved by the said Commissioner on or before November first, nineteen hundred and eight, and failure on the part of the Riverton Consolidated Water Company so to do shall be understood and deemed to be an admission on the part of said company of its inability to fulfil its charter obligations, and the Commissioner of Health will so un-

derstand it and proceed accordingly in the interests of public welfare: provided, however, that if satisfactory evidence shall be forthcoming that November first, nineteen hundred and eight, is too short a time in which to make such beginning in construction then the Commissioner of Health may extend the time, but not for any long period, and then only when specified by the company that it will be able to carry out the terms of this decree in the immediate future.

ELEVENTH: The water company shall at the close of each season's work file a plan of lateral street extensions of its pipe system, together with any other information in connection therewith that may be required, in the office of the Commissioner of Health, to the end that the State Department of Health may always be informed as to the extent of the water works system and the public use thereof.

Permission to supply the Shiremanstown Water Company with water at any point in Lower Allen township is hereby denied. The application now under consideration of the Shiremanstown Water Company, for permission to obtain its supply from the Riverton Consolidated Water Company, must be granted, if granted at all, in the face of ample evidence that the Riverton Consolidated Water Company will be capable of furnishing an ample and pure supply to Shiremanstown Water Company, at all times and under all conditions.

TWELFTH: The water company shall forthwith keep a daily record of the operation of its entire water works system, including the present river pumping station, on forms satisfactory to the Commissioner of Health, and copies thereof shall be filed in the office of the Commissioner of Health. If at any time it becomes apparent that the water works system or any part thereof, or the water supplied thereby, is prejudicial to public health, then the Riverton Consolidated Water Company shall adopt such remedial measures forthwith as the Commissioner of Health may advise or approve.

The Commissioner of Health will notify the owners of sewers hereinbefore mentioned that within thirty days the discharge of sewage into the waters of the State shall cease, also the garbage disposal into the waters of the State and on the banks of the river shall be discontinued forthwith.

The Commissioner of Health will also notify the local authorities of each borough of the danger of the use of abandoned wells or receptacles for sewage and advise that the matter of the disposal of sewage should receive the careful attention that it deserves in each municipality.

Harrisburg, Pa., August 18, 1908.

LOWER ALLEN TOWNSHIP, CUMBERLAND COUNTY.

Riverton Consolidated Water Company.

This application was made by the Riverton Consolidated Water Company of the village of Riverton, Lower Allen Township, Cumberland County, for approval of plans for a water filtration plant and for improvements to the Company's distributing system.

It appears that these plans were submitted in compliance with the terms of a decree issued by the Commissioner of Health on August eighteenth, one thousand nine hundred and eight, to the said Water Company.

The proposed improvements contemplate the following:

FIRST: The securing of an additional supply of water from the Yellow Breeches Creek, the supply to be taken at a point south of New Cumberland, at a mill dam now owned by the Riverton Consolidated Water Company.

SECOND: The construction of a pumping station and purification works at the mill site above mentioned.

THIRD: The laying of a new force main from the purification works and pumping station above mentioned to a new elevated reservoir to be constructed on top of the high ground north of White Hill and about half a mile west of the present Fort Washington Reservoir.

FOURTH: The laying of additional street mains in White Hill, Lemoyne and New Cumberland, and the making of connections between the new high pressure systems, the present Fort Washington reservoir, and the street mains, to increase the pressure throughout the district, and give a more copious supply of water, and provide satisfactory fire protection.

FIFTH: The abandonment of the pumping station on the west bank of the Susquehanna River above the Walnut Street Bridge.

The proposed new works near New Cumberland will consist of purification works and pumping machinery, the capacity of the works to be built immediately being five hundred thousand gallons per day from this source.

The purification works contemplate the preparatory treatment of the water by:

(a) Subsidence to remove the coarse suspended and floating matter and:

(b) Rapid filtration through coarse grained filters, with or without the use of a coagulant, as may be proper.

The water will be taken from the race of the mill by a centrifugal pump, and discharged directly upon the roughing filters, or upon them after passage through a coagulating and deposit chamber. When the turbidity of the raw water is less than one hundred parts per million, no coagulant will be used; when less than

about fifty, the water will usually be passed directly upon the roughing filters and when more than one hundred coagulation must be resorted to, using sufficient aluminum sulphate to reduce an effluent from the roughing filters with a turbidity of not over twenty-five parts per million.

The effluent from the rapid, or roughing filters is to be further purified by slow sand filtration, the filters being operated at a relatively high rate. This plant is, in general, similar in style to that installed recently, (and now in successful operation) for the purification of the water supplied to the Borough of Steelton, Pennsylvania.

The capacity of the different parts of the purification works will be as follows:

The deposit chambers are ten feet wide, thirty-one feet long and nine feet deep with a capacity of twenty-seven hundred and ninety cubic feet, or twenty-one thousand gallons or one hour's supply when the plant is operated at the rate of five hundred thousand gallons daily.

There will be three filters nine feet by twelve feet in plan and nine and five-tenths feet deep, each having a surface area of one hundred and eight square feet, two hundred and forty-nine hundred thousandths of an acre. Two filters in use will yield five hundred thousand gallons daily when operating at a rate of one hundred million gallons per acre per day the third filter being out of service for washing. These filters can safely be depended upon to yield fifty per cent. more water than the nominal capacity of five hundred thousand gallons daily.

There will be four filters each twenty-seven and five-tenths feet square, arranged in the form of a square, with a sand washing plant located in the center of the group. The net area of each filter will be seven hundred and sixteen square feet, one hundred and sixty-five ten thousandths of an acre. When three of the four filters are in service there will be five hundredths of an acre in use, which will, at a rate of ten million gallons per acre daily, yield five hundred thousand gallons of filtered water.

The immediate demands upon this plant will not exceed the furnishing of about two hundred and fifty thousand to three hundred thousand gallons of water a day.

The filtered water will flow to a small pure water reservoir on top of which will stand a triplex power pump belt driven from the line shaft of the mill, the pump having a capacity of five hundred thousand gallons daily, at maximum speed, but having three speeds at which it can be driven from the line shaft.

The force main to the stand pipe will be twelve inches in diameter from the pumping station to Market Street in Camp Hill, and thence sixteen inches in diameter to the elevated reservoir, which will be located twenty-one hundred and fifty feet west of the Fort Washington reservoir, on the highest part of the ridge. The elevation of the ground at this point is five hundred and twenty-nine feet above sea level, and the surface of the water in the stand pipe, when full, will be five hundred and eighty feet above sea level.

The static lift on the pumps will thus be two hundred and eighty feet, and the friction head for the delivery of five hundred thousand gallons of water daily to the elevated reservoir eleven feet making a total of two hundred and ninety-one feet. For the delivery of one million gallons daily the total lift would be increased to three hundred and twenty-four feet.

The elevated reservoir, to be located on the high ridge west of the Fort Washington reservoir, will be of reinforced concrete lined with a riveted sheet steel shell protected from corrosion by a reinforced cement lining.

The diameter of the reservoir is to be forty feet, inside with a shaft, six feet in diameter, passing centrally downward through it, to the foundations, and forming one of the supports.

The capacity of the reservoir, when full, will be two hundred thousand gallons.

The reservoir will be supported on arched piers and reinforced columns and will be covered with a domed roof having a ventilator on top, with screened openings, and a cast iron manhole head and cover.

The filtered water from the pumps will be delivered to the stand pipe through a twelve inch flanged pipe rising up through the central well and discharging over the top of the same into the reservoir.

The outlet from the reservoir to the high service district will be at the bottom of the reservoir through a twelve inch check valve on a branch pipe connected with the twelve inch vertical force main. This arrangement will insure circulation in the reservoir.

A second twelve inch pipe will rise up through the central well passing the reservoir at the bottom and having a twelve inch valve thereon, and, also, a vertical branch, open at the top forming an overflow to the reservoir. This overflow pipe will lead to the Fort Washington reservoir, and will be the supply pipe through which this reservoir will be filled with filtered water.

A blow-off connection on this pipe will permit it to be used for cleaning the reservoir, if necessary.

In order to secure better pressures in Lemoyne and Riverton a new ten inch main will be laid from the Fort Washington Reservoir to Lemoyne, being connected with the main on Herman, Hummel and Bossler Streets, proper circulation in the street mains in Lemoyne being secured by laying six inch connecting mains in Bucher, Clinton and Lorne Streets, from Herman to Bossler, connecting at each intersection, control valves being supplied where necessary.

In New Cumberland it is proposed to provide six inch connections between the new twelve inch force main and the six inch mains on Third and Sixth Streets,

install new fire hydrants on the high pressure line and provide new four inch circulation mains in Second and Sixth Streets, with control valves, to give an additional supply and better pressure.

At White Hill Station it is proposed to place in the new eight inch main leading to Shiremanstown a valve each side of the connection between this eight inch main and the new twelve inch force main, by this means the high service pressure can be turned into the Lemoyne mains, if necessary, and can be used customarily to give sufficient pressure for satisfactory service in Shiremanstown, where about sixty pounds pressure would be expected during the day time, rising to seventy pounds in the night.

Between White Hill Station and the new elevated reservoir the twelve inch main would follow westwardly along this street north of the Cumberland Valley Railroad to Heyd Street being connected with the four inch main in Main Street; thence northerly on Heyd Street to Market Street, where a connection would be made with the existing four inch main; thence easterly along the turnpike and following the alignment shewn on sheet thirteen of the plans, to the elevated reservoir, with proper connections and valves to control the supply.

On the abandonment of the pumping station on the Susquehanna River the present eight inch force main to the Fort Washington reservoir will be converted into a supply main to Wormleysburg, proper connections being made therefor.

It is also the intention, in the near future, to take up the four inch main in the turnpike, from Heyd Street westwardly for about three thousand feet, replacing the same with ten inch cast iron pipe to give better pressure.

It has been determined that the plans hereinbefore described provide for improvements which will not be prejudicial to public health, and the same is herein and hereby approved and a permit is issued therefor, under the condition that all of the conditions applicable thereto and specified in said decree of August eighteenth, one thousand nine hundred and eight, are applied and put in full force with respect to the plans herein approved and subject to the additional conditions as follows:

FIRST: The filter plant shall be constructed only under the immediate and responsible supervision of the engineer who designed the plant or some other expert equally competent to perform the services, and after the works are built they shall be operated for one year under the responsible supervision of some expert in order that the attendants at the filter plant shall be given ample opporunity to become thoroughly schooled in the operation of the filter plant.

SECOND: Daily record of the operations of the filter plant shall be kept on blank forms satisfactory to the Department of Health and whenever required copies thereof shall be filed in said Department's office.

It is the intention of the Department of Health to make regular inspections of the filter plant and if necessary, in the interests of the public health, to establish rules and regulations for the operation thereof in so far only as the public health would be concerned. The Water Company shall adopt such requirements and put them in force, and at all times render assistance to State officials in making investigations. If at any time, it becomes necessary, in the opinion of the State Department of Health, that enlargements, additions or alterations shall be made in the works or any part thereof, then the water company shall make such extensions, alterations or improvements as the Department of Health may advise or approve.

Harrisburg, Pa., November 12th, 1908.

McKEESPORT, ALLEGHENY COUNTY.

This application was made by the City of McKeesport, Allegheny County, Pennsylvania, and is to extend and enlarge the municipal water main system.

It appears that on March seventh, nineteen hundred and seven, the Commissioner of Health approved plans for a water softening and filtration plant for the city and issued a permit therefor under certain conditions among which were the following:

FIRST: That a complete set of plans of the driven well system, pumping station plant, intake well and piping, force main, distributing reservoir, high service pumping station and plans of the pipes in the high and in the low service districts of the existing water works system shall be prepared without delay and filed with the Commissioner of Health, together with a satisfactory report of said works.

SECOND: That the proposed mechanical filtration plant is hereby approved with the provision that the clear water basin capacity shall be increased to not less than two hundred thousand gallons, and that a new pump well of ample dimensions shall be built at the pumping station to which all filtered water shall be delivered and from which it shall be taken by the pumping engines. Plans for the enlarged clear water basin and the new pump well shall be submitted to the Commissioner of Health for approval.

THIRD: That in the event of the substitution of bidder's plans for the mechanical filter plant herein approved, then such plans shall be submitted to the Commissioner of Health for approval before the said works are constructed.

FOURTH: The admission of the raw river water to the water pipe system of the town or to any part of the works except the water softening or filtration plant is prohibited except in extraordinary emergencies. This obtains also with respect to

the ground water. To safeguard the public interests there should be an emergency intake from the river to the new pump well. The valves on this intake shall be closed under seal. Whenever used the Commissioner of Health should be notified. Plans for the quick introduction of raw river water into the filtered water pump well, which introduction may be by gravity or pumping, shall be submitted to the Commissioner of Health for approval.

FIFTH: Plans of the works when built as herein provided for shall be submitted in detail and filed with the Commissioner of Health, together with such other information in connection therewith as he may require.

SIXTH: A chemist and skilled attendant shall be placed in charge of the operation of the water softening and filter plant. Weekly reports of said operation shall be submitted to the Commissioner of Health on blanks to be furnished by the State Department of Health.

The city has complied with the conditions in stipulation Number One.

The city has also increased the capacity of the clear water basin to over two hundred thousand gallons and a new pump well of ample dimension has been built at the pumping station to which all filtered water is to be delivered and from which it is to be taken by the pumping engines on the town service. Plans for these structures are now before the Commissioner of Health.

The clear water basins are located as previously described, in the said permit of March seventh, nineteen hundred and seven, in the filter house under the filters. However, the depth of the basin has been increased to about twelve feet, giving an effective capacity of about two hundred and seventy thousand gallons.

The new filtered water pump well is located between the raw water intake well and the pumping station. Because of lack of space between the two, the filtered water pump well is made narrow and long. Its length is fifty feet, eleven and five-tenths feet wide and about twenty feet deep. A thirty inch pipe line is to deliver the filtered water to the well. This well is open on top, the opening being four feet eight inches wide and extending the entire length. The part roofed over is adjacent to the pump house. To prevent ordinary freshet water from flowing into the well, there is built around the opening a concrete wall four feet high, the top of the well being even with the surface of the ground. The top of the wall is one foot nine inches lower than the flood level of February twenty-third, eighteen hundred and ninety-seven and five feet four inches lower than the flood level of March fourteenth, Nineteen hundred and seven. Both of these floods put the pumping machinery out of commission. As the plant now exists flood water would enter the pumping station and the filter house and the softening plant before it reached the level of the wall about the filtered water pump well.

It is understood that the city contemplates the erection of walls to protect the water works at the pumping plant from damage or flooding. It is important that such plans should be perfected and executed without delay. The small storage afforded by the reservoir on the hill—twenty-four hours' supply—in connection with the possibility of the purification and pumping plant being out of commission for more than twenty-four hours emphasizes the point. An extended conflagration coincident with the high freshet flow of the river would prove most disastrous to the city were there no flood protection works at the plant.

The mechanical filters being built in accordance with the plans now before the Commissioner of Health differ from the filter plant described in the said permit of March seventh, nineteen hundred and seven, in the following particulars:

The delivery main from the water softening plant to the adjacent filters is by means of a rectangular re-inforced concrete conduit in place of the thirty inch pipe. Each of the six filters is twenty-four feet by eighteen feet with a capacity of one million gallons daily. There is thirty-four inches of sand supported by eight inches of gravel over a manifold system bedded in a concrete floor of the filter and connected to a ten inch outlet. The air system consists of one-half inch transversed piping six inches on centres, perforated on the underside and placed two inches above the collecting manifold. The collecting and distributing troughs are three in number for each filter unit. They extend on each side of a central channel built the full length of the filter. They are parallel, eight feet apart on centres and their tops are sixteen inches above the level of the sand in the filter.

The project for the quick introduction of raw river water by the purification plant into the filtered water pump well which the city has introduced and for which approval is requested is as follows: From the raw river receiving well adjacent to the filtered water pump well there are three pipe lines leading to the three main pumping engines in the pump house and in use on the town service. Two of these pipes are twenty inches in diameter and each pipe leads to a three million gallon Blake pump. The other pipe is twenty-four inches in diameter and leads to a five million gallon Wilson-Snyder pump. These three pipe lines pass through the filtered water pump well and by an arrangement of valves and branches, either filtered water may be drawn from the filtered water well which will be the ordinary use of the pipes, or in extreme emergencies, and by the use of the valves, the filtered water may be shut off and the raw river water may be drawn.

The city's auxiliary supply from drilled wells on the premises has been abandoned. The circular well in which was installed the pumping machinery for drawing the water from the ground is now used to house the centrifugal pumps direct connected to Delaval steam turbine engine. There are two of these pumping engines, each

rated at seven million gallons per twenty-four hours. They will supply the raw river water from the intake well to the water softening plant. These engines need protection from floods as well as those in the old pump house of the main station.

The twenty-four inch intake which it is the intention of the city to build from the raw water intake well out into the river far enough to avoid contamination from the sewers discharging above this point will not be built for the present. The old sixteen inch intake is to be used until it shall have proved inadequate or unsafe.

The distributing reservoir is located about one-half a mile from the pumping station. It is on a hillside, three sides of the reservoir being an embankment. The structure is masonry lined and about two hundred feet square with a depth of twenty-six feet and has a capacity of five million gallons.

There is a sixteen inch force main which delivers the water from the pumping station into the reservoir. It is reported that the city intends to substitute this by a twenty inch pipe. A new twenty-four inch force main has recently been constructed by the city from the pumping station towards the centre of the city where it connects with the distributing mains. Both of these force mains are by-passed to permit of the pumping of water either directly to the reservoir or directly to the city mains with the surplus overflowing into the reservoir.

The high service pumping plant occupies a small portion of a plot of ground owned by the city. It is adjacent to the reservoir and the land is available and could be used for a new reservoir. It is reported that an additional storage capacity of about five million gallons could thus be secured. It is understood that this addition is contemplated. Plans should be prepared and submitted to the Commissioner of Health for approval.

There are in service about fifty-eight and five-tenths miles of main pipes in the streets, ranging in size from four inches to thirty inches in diameter. This system fairly well covers up the built-up portion of the city. However, many of the mains are too small to meet the increasing demand put upon them, especially in case of a large fire. It is the intention of the Water Board to replace many of these small mains by larger ones, to extend the service into the outlying districts, to provide by-pass connections to meet emergencies and local fluctuations in consumption. Permission to do these things is requested.

While the present sixteen inch intake may prove adequate, its short length makes the danger of excessive pollution by sewage from the city sewers above it very great. The new twenty-four inch intake shown on the plans which were approved by the Commissioner of Health, should be constructed without delay.

It has been determined that the plans for the improvements at the purification plant and pumping station will not be prejudicial to the public health and it is hereby and herein approved and a permit issued therefor and for the extension of the street main system in the city under the following conditions and stipulations:

FIRST: Complete plans of the intakes, water softening and purification plant and the pumping stations, together with the arrangements of pipes and valves, shall be filed with the Commissioner of Health, showing said works as built and this filing shall be done not later than six months from the completion of the improvements. At the close of each season's work plans of the water pipes laid during the year shall be prepared and filed in the office of the State Department of Health, together with any other information in connection therewith that may be required, to the end that the Commissioner of Health shall always be adequately informed of the extent of the water works system and the public use thereof. Weekly reports of the operation of the water works system shall be kept on blank forms satisfactory to the Commissioner of Health and copies thereof shall be filed in the office of the State Department of Health.

SECOND: The emergency intake between the river or the receiving well and the new filtered water pump well shall not be used except in extraordinary emergencies. Whenever used the Commissioner of Health shall be notified and all due precautions taken by the city to protect the public health in so far as this may be done.

THIRD: The city shall devise a method to reduce and if possible, eliminate the danger from floods at the purification and pumping plant. Plans for such protective work shall be prepared without delay and submitted to the Commissioner of Health for approval.

FOURTH: Before any enlargement of the existing storage reservoir is made plans therefor shall be submitted to and be approved by the Commissioner of Health.

FIFTH: The new twenty-four inch intake shall be constructed without delay in accordance with the plans for the purification works approved by the Commissioner of Health on March seventh, nineteen hundred and seven.

SIXTH: A suitable cover shall be placed over the clear water pump well at the main pumping station to obviate any possible accidental contamination of the filtered water at that point.

SEVENTH: It is the intention of the State Department of Health to make frequent examinations of the water works system. If at any time in the opinion of the Commissioner of Health, the water supply system is not performing its work efficiently, or the water being supplied by the city is or may be injurious to public health, then the city of McKeesport shall adopt such remedial measures as the Commissioner of Health may approve or suggest.

Harrisburg, Pa., October 15th, 1908.

41—17—1908

MARCUS HOOK, DELAWARE COUNTY.

Chichester Water Company.

This application was made by the Chichester Water Company of the borough of Marcus Hook, Delaware County, and is for permission to install a system of water works for the supply of water to the public in said borough.

It appears that on October first, one thousand nine hundred and seven, the New Chester Water Company made an application for permission to extend its water works system and supply water to the public within the borough of Marcus Hook, Delaware County, Pennsylvania. It was determined at that time by the Commissioner of Health that the New Chester Water Company appeared to have no right to supply water to the public in the borough of Marcus Hook. Accordingly the said water company was notified that the Commissioner of Health could not entertain an application made by it for permission to supply water in Marcus Hook until such time as the Company was authorized to supply water to said borough.

In the meantime, the New Chester Water Company had proceeded to extend its mains to the borough and had laid in the highways therein about three and a half miles of ten, eight and six inch pipes. Following the receipt of the notification from the Commissioner of Health that the New Chester Water Company had no rights in Marcus Hook borough, application by persons interested in the New Chester Water Company was immediately made for the incorporation of the Chichester Water Company. The application was made for the purpose of legalizing the supply of water by the New Chester Water Company in Marcus Hook.

On December nineteenth, one thousand nine hundred and seven, the Chichester Water Company was duly authorized to supply water to the public in the borough of Marcus Hook, its source of supply to be the Delaware River, the water to be taken therefrom at the present pumping station of the New Chester Water Company in the city of Chester.

On December thirty-first, the secretary of the new company notified the Department about its new charter and requested that a permit be granted for the use of the water pipes laid in the streets of Marcus Hook borough and for the supply of water to the public as provided by charter, and on March seventh, One thousand nine hundred and eight, a formal application therefor was made by the Chichester Water Company.

Marcus Hook borough lies on the shore of the Delaware River about three miles southwest of the city of Chester, all in Delaware County. The borough is adjacent to and north of the Pennsylvania-Delaware State line. It is a very old settlement dating back to about seventeen hundred. First incorporated into a borough about eighteen hundred and seventy, it subsequently gave up its incorporation but was again re-organized into a borough in eighteen hundred and ninety-two. Its population then was less than a thousand. In nineteen hundred the census gave the population as twelve hundred and nine. Within the last five years, following the construction of oil refineries and other industrial works, its growth has been more rapid. There are at least fifteen hundred residents in the community now. A number of the employes live in Philadelphia and Chester.

The local authorities hope by promoting public improvement, such as water works and sewerage works, to build up the town. Previous to the installation of the present water system no general system had been built. In eighteen hundred and ninety-two the Marcus Hook Water Company was incorporated but the charter lapsed because the company failed to take any active steps toward furnishing the public with water. Prior to the rights vested in the Chichester Water Company now under consideration, the Marcus Hook Water Company's charter was the only one ever granted covering this territory. The Linwood Water Company, incorporated in eighteen hundred and ninety-five for the supply of water to Lower Chichester Township from which the borough of Marcus Hook had been previously organized, sold its franchise and all its property in nineteen hundred and six to the New Chester Water Company and it was under this Linwood Water Company's franchise that the New Chester Water Company thought it had the right to supply the borough of Marcus Hook.

Investigations by the Department indicate that the citizens of Marcus Hook stand in need of a supply of water for domestic, municipal and fire purposes. Heretofore, the population has been dependent upon wells, shallow, located on private properties throughout the town, and in numerous instances in close proximity to cesspools or shallow earth privy vaults which menace the purity of the well water. Some typhoid fever has been attributed to the contamination of these private sources of drinking water.

Nothing smaller than a six inch pipe line has been laid in the streets. Fire hydrants have been installed. It is understood that a pressure of seventy-two pounds will be available at Marcus Hook. A franchise has been obtained from the borough. It was granted to the New Chester Water Company, under which said company laid the mains during the summer of nineteen hundred and seven. It is presumed that the Chichester Water Company has become possessed of the water pipes and appurtenances, and will assume the obligations under which the New Chester Water Company laid the pipes in Marcus Hook.

The New Chester Water Company's plant consists of a Delaware River intake, two pumping engines of five million gallons capacity each, a twenty and twenty-four inch rising main about three and a half miles long, terminating in subsiding reser-

voirs located on Harrison Hill back of Chester, each reservoir holding eight million gallons, a mechanical filter plant of a daily capacity of six million gallons, a filtered water reservoir of two million gallons capacity and a system of gravity distribution in Chester City, Upland borough and Lower Chichester township. The daily consumption averages less than three million gallons and the population supplied approximates thirty-six thousand people. The source of supply is polluted by Philadelphia sewage. The filter plant was installed in nineteen hundred and two and nineteen hundred and three. The water which the Chichester Water Company is authorized by its charter to obtain from the New Chester Water Company will be delivered at the boundary line between Lower Chichester township and Marcus Hook borough, and the supply should be as potable for domestic uses as any supply which could be economically obtained in the vicinity.

To quite a degree the health and even life of the water consumers in the district furnished with drinking water by the New Chester Water Company depends upon the efficiency of the aparatus which said company operates and maintains to remove the sewage poisons known to exist in its source of supply, the Delaware river, and render the water potable. Any accident occurring to the plant whereby raw river water might be introduced into the homes of the district would be likely to imperil public health and might be followed by a fatal epidemic. It is the duty of the Commissioner of Health to preserve the purity of the waters of the State for the protection of the public health. However, the discharge of Philadelphia's sewage into the Delaware river and its tributaries cannot be discontinued except it be most gradually and under some plan necessarily requiring several decades for its consummation. Therefore, the New Chester Water Company must exercise constant vigilance in the operation of its purification plant. The extension of this water supply to Marcus Hook might easily become a public calamity to that borough. State sanction of the supply must provide safe guards against an inferior quality of water. The petitioners should not engage in the business of selling water, the quality of which is a matter beyond its control. There should be an agreement in writing between the Chichester Water Company and the New Chester Water Company, whereby the latter shall guarantee under a suitable and sufficient bond to furnish water to the Chichester Water Company under conditions and tests satisfactory to the State Commissioner of Health. It would not do to deprive Marcus Hook of its supply for manufacturing and supply purposes and therefore there appears to be no other practicable means of guaranteeing a constantly pure water or one approaching nearest to constant purity than by such an agreement as proposed.

The petitioners have not submitted a plan of the existing water pipes in Marcus Hook borough or of extensions that may be made thereto from time to time.

It has been determined that the proposed water works system and the supply therefor in the borough of Marcus Hook will not be prejudicial to the public health, and a permit is hereby and herein granted therefor under the following conditions and stipulations.

FIRST. This permit shall not be operative until the Chichester Water Company shall have entered into an agreement with the New Chester Water Company, whereby the latter shall guarantee to furnish the former with a sufficient quantity of water, the purity of which shall be satisfactory to the State Commissioner of Health. Tests of this water shall be made by the Chichester Water Company every two weeks and copies thereof filed in the office of the State Department of Health. A copy of said agreement shall also be filed in said office.

SECOND. On or before June first, one thousand nine hundred and eight, the Chichester Water Company shall prepare a plan showing the boundaries of the borough of Marcus Hook and the streets and the water pipes laid therein, and file said plan in the office of the State Department of Health. At the close of each season's work a plan of the water mains laid during the year shall be made and sent to the Commissioner of Health, to the end that there shall be a complete record in said office of the extent of the Chichester Water Company's water works and the number of people in the borough dependent upon such supply.

THIRD. Ample facilities for the complete drainage of the water pipe system or of parts thereof shall be provided and the location of the facilities and of all gates and blow-offs shall be indicated on the plan to be filed in the State Department of Health on or before June first, one thousand nine hundred and eight.

FOURTH. If at any time in the opinion of the Commissioner of Health the water supply, or the water works, or any part thereof, has become prejudicial to the public health, then the Chichester Water Company shall adopt such remedial measures to protect the public health as the Commissioner of Health may approve or suggest.

FIFTH. Regular inspections will be made by the New Chester Water Company's system and supply by a Department officer. The Commissioner of Health may suggest rules and regulations to govern the supply of water to the public in so far as the public health is concerned. The Chichester Water Company shall conform to any such orders, rules or regulations in so far as they may relate to the supply of water to the public in Marcus Hook borough.

SIXTH. This permit is issued on the express stipulation that the proposed operations of the Chichester Water Company are wholly within its charter rights.

Harrisburg, Pa., March 30, 1908.

MATAMORAS, PIKE COUNTY.

Matamoras Citizens Water Company.

This application was made by the borough of Matamoras, Pike county, and is for permission to install a water works system and to supply to the public in said borough.

It appears that the borough of Matamoras, of fifteen hundred population, is located in the extreme eastern corner of Pike county, on the banks of the Delaware, opposite the city of Port Jervis, New York (population, ten thousand), which, together with Matamoras, constitutes a railroad community. Matamoras is strictly a residential town. The Erie Railroad extends from New York to Port Jervis and on up the valley of the Delaware. Port Jervis is the terminus for many of the passenger trains from New York, and is also the site of extensive yards for the re-making of through freight trains and of large repair shops, so that the railroad furnishes employment for the support of the greater part of the population of Port Jervis and Matamoras. There are also in Port Jervis half a dozen manufactories each employing about a hundred hands. A highway toll bridge connects Port Jervis with Matamoras, and from the latter town there extends down the valley of the Delaware, connecting with the Pennsylvania Railroad and the Delaware, Lackawanna and Western Railroad at Stroudsburg, a much traveled highway, which is the only means of communication through the valley.

For many miles above Matamoras the Delaware follows a southeasterly course while immediately below it turns sharply and follows a southwesterly course for twenty-five miles along the foot of a well-defined mountain ridge in Pennsylvania parallel to the river. Matamoras is located entirely on a flat strip of land in this angle of the river between it and the foot of these hills. The hills are of shale formation and the flat is of fine sand underlain by gravel. The flat is at an average levation of about twenty feet above the river, which has never reached this height except when jammed with ice. These ice jams have done much damage to both banks of the river, as a result of which a dyke faced with riprap has been constructed along the Port Jervis shore, and it is said a State appropriation has been secured for a similar structure along the Matamoras bank.

Matamoras has grown from a few houses at the time of the building of the first highway bridge, in eighteen hundred and seventy-two, until now it has a population of fifteen hundred or more, during which time the highway bridge has been twice destroyed by floods and rebuilt. The town was incorporated as a borough on January eighteenth, nineteen hundred and five.

Delaware Drive extends southeasterly along the river front from Diller's Brook at the northwestern limit of the borough to Pennsylvania Avenue and the highway bridge. The streets parallel to Delaware Drive are named in order from First Street to Tenth Street, which is the southwestern borough limit. The cross streets are named in order from Avenue "A," at the northwestern end of the borough, to Avenue "T," at the southeastern end, with the exception of Pennsylvania Avenue, which runs between Avenues "K" and "L." The streets thus planned extend over the entire borough, which has an area of about four hundred acres and is nearly square in shape. The area laid out in streets and built up includes only about one-third of the borough in the northern part. The general surface slope in the borough is to the south away from the river front of the town to a depression in the flat extending easterly to the river below Matamoras. Few or no storm drains have been built, and the natural grades are light, and yet it is said that storm water seldom creates a nuisance in the town owing largely to the porosity of the soil.

Perhaps a half dozen houses along the river front have sewer pipes leading to the river, while a few others (although the number of these is said to be increasing) are sewered to percolating cesspools. A very few houses have inside flush closets and practically every house has an outside privy, which are almost exclusively of the loose vault type. Waste water is for the most part disposed of on the surface of the ground, where it is said not to create a nuisance owing to the porosity of the soil and the houses not being built closely together.

The water supply is at present obtained from private wells, of which there are estimated to be two hundred and forty in the town, one for nearly every house. These wells are, almost without exception, either driven or dug, there probably being rather more of the latter type.

The Matamoras Citizens' Water Company was incorporated with a capitalization of seven thousand dollars on June seventeenth, nineteen hundred and three, to exist for a term of ninety-nine years, for the purpose of supplying water within the township of Westfall, from which township the borough of Matamoras has since been organized. No contract has been made between the water company and the borough, although one has been drawn up providing for the proper laying of the pipes and for taking of water by the borough for fire protection and the furnishing of the same by the water company, which agreement it is said both parties are ready to sign whenever the water company is in position to carry out its part.

The water supply is to be obtained from one or two drilled wells, or from both of them, depending upon future investigations and the demands upon the system.

West of Matamoras is a bowl-shaped valley in the hills. This basin is two hundred feet or more higher than Matamoras, has an area of three-quarters of a square mile, and opens to the river valley at the northeast. It is sparsely populated, partly cultivated and partly in scrub timber, and is drained by Driller's brook,

which enters the river just above Matamoras. Just northwest of the borough, in line with Third Street and about one hundred feet west of Driller's brook, below the well-defined basin, the water company drilled a well about two years ago. The ground at the site of this well is at an average of fifteen feet above the town and above the bed of Driller's brook. The well is said to be eight inches in diameter and two hundred and two feet deep, and to be cased in sand and gravel for a depth of eighteen feet, and to extend the remainder of its depth through shale rock, in which are the water-bearing strata, principally at a depth of one hundred feet and more. The well is said to have been tested after being completed and to have yielded continuously for twenty-four hours one hundred and twenty-five to one hundred and thirty gallons per minute, which was the maximum capacity of the testing pump used. During the greater part of the year water flows from the well at the surface, though not in any great quantity. During the test the water fell in a short time to a depth of one hundred and fifteen feet, from which it varied little or not at all during the remainder of the twenty-four-hour test. The nearest building to this well is a dwelling about one hundred and fifty feet distant up the hillsides.

It is stated that it is thought that further investigations may indicate that the possibility of drilling further up the hillside in the mouth of the valley already described an artesian well, which will yield without pumping a flow sufficient to meet the demands of the water consumption, at least during the greater part of the year. The exact location of this proposed well was not known by the water company officials.

A concrete reservoir was constructed by the water company a year or so ago on the hillside about half way between the sites of the two wells. This reservoir is about forty-five feet in diameter, being octagonal in shape and ten feet deep. It is provided with a six-inch overflow pipe and with a single inlet and outlet pipe ten inches in diameter, so it is said. A small pipe has also been placed in the wall a couple of feet from the bottom as a means of connecting the reservoir with any other one which it may be desirable to build in the future. The reservoir is a massive, apparently substantial, concreate structure, with a frame roof. The elevation of the bottom of the reservoir is about five hundred and eighty feet above tide; the average elevation of the town, four hundred and forty feet.

The method of connecting the proposed upper well with the reservoir has not been decided upon. The water from the lower well, if this is needed, is to be pumped into the ten-inch gravity supply pipe to the town, which pipe is to pass near the well. However, the water may be raised from the well to the reservoir in two lifts, in which case a rectangular concrete basin of ten thousand gallons more capacity, already constructed near the well, may be used as an intermediate receiving basin and pump well. The details of the pumping station have not been designed.

From the connection at the proposed pumping station the main ten-inch pipe (or possibly eight inch) is to extend southeasterly across Driller's brook and in Third Street, a total length of one thousand seven hundred and twenty-five feet to Avenue "F," being connected with several cross pipes of the distributing system. At Avenue "F" the main reduces to eight inches in diameter and continues in Third Street about thirteen hundred feet to an eight-inch cross main in Pennsylvania Avenue, a six-inch pipe continuing about five hundred feet farther in Third Street. The distributing system is to have no dead ends. It is to include in all, below the connection of the pumping station to the main, about seventeen hundred and twenty-five feet of ten-inch pipe, twenty-seven hundred and fifty feet of eight-inch, seven thousand feet of six-inch and seventeen thousand eight hundred feet of four inch.

No plans have been filed with the application showing the location of the wells, the construction of the existing well, the arrangement at the pumping station, the reservoir, the connections between the wells and the reservoir, and the gravity main and distributing system, with the location thereon of valves, low points, blowoffs for draining and fire plugs, all of which plans should have been filed with the application and should, under any condition, be approved by the Commissioner of Health before the water works are constructed. The only plan submitted is a layout of the distributing system, showing the sizes of pipes to be used, but without other details.

Very many of the buildings of the town being located within fifty feet of each other, the practice of disposing of sewage in loose privy vaults and on the surface of the ground or in percolating cesspools, and the method of obtaining water for domestic purposes by means of dug or driven wells from the thirty foot surface stratum of porous sand and gravel render the quality of these various water supplies doubtful. The report of a local physician, in agreement with the report of a member of the local Board of Health, is to the effect that typhoid is of rare occurrence in Matamoras and that the majority of the patients have been railroad men, who probably contracted the disease away from home. This, however, is no assurance of the continuance of the purity of the well waters in view of the increasing number of cesspools, nor indeed that many of the wells are not at present contaminated with sewage. The bringing in of a supply of pure water from a distance would certainly be in the interests of public health, and if it were generally

used and the local wells abandoned, the sandy soil should for some time afford a way of satisfactory disposing of sewage in cesspools at small intial costs for sewerage.

There is every indication that the proposed water supply to be obtained from deep drilled wells in shale rock will be satisfactory and healthful if proper care is taken in protecting the wells from surface pollution.

Another urgent reason for the proposed introduction of a public water supply in pipes is that fire protection may be afforded and the fire insurance rates reduced, which rates are now considerably above the rates for Port Jervis. Although the efficiency of the water works for fire protection is but indirectly related to the function of the works to furnish water for domestic purposes, the Department feels called upon to direct the attention of the water company and the borough officials to the following features of the water system as a means of fire protection:

The average elevation of water in the reservoir above the surface of the ground in Matamoras of from one hundred and forty feet to one hundred and forty-five feet, respectively, with the reservoir about empty to half full, would afford a static pressure in the town of from sixty-one to sixty-three pounds per square inch. If not more than twenty plugs are distributed uniformly over the built-up part of the town, many points in Matamoras could be reached from the nearest plug only by five hundred feet or more of hose. Even if the static pressure of from sixty-one to sixty-three pounds, or sixty-five pounds for a full reservoir (the greatest pressure the reservoir could ever produce) were obtainable at the plugs, allowing for no loss of head in friction during the flow of the water in the pipes, this pressure would be insufficient to furnish through three hundred feet or more of two and a-half-inch hose a fire stream such as fire underwriters assume as a standard. It is, therefore, apparent that the pipes of the system should be designed so that as little head as possible may be lost in friction, and that there is no doubt but that at least a ten-inch pipe should be used for the gravity main and the principal main of the distributing system, instead of an eight-inch pipe, the use of which is said to have been considered and in which the loss in friction would be materially greater, thus reducing the efficiency of the fire protection. Although even a ten-inch gravity and distributing main would not afford in connection with the present reservoir a standard fire stream, this sized pipe even after it has been in service several years should furnish from three to five fairly efficient fire streams for a small town of low buildings.

It should also be mentioned that the capacity of the present reservoir, about one hundred thousand gallons, would be insufficient to provide storage for fire protection and for the inequalities of consumption for domestic purposes during the day, for even half a day, so that this fact should lead the water company to provide pumping facilities or means of obtaining water from the proposed upper well.

A satisfactory means of obtaining a thoroughly efficient system for fire protection would be to construct another reservoir at a greater elevation or to install a pumping outfit of sufficient capacity to furnish water for fire purposes under direct pressure from the pumps.

A pipe system adequate to furnish fire protection would, of course, meet the ordinary demands upon the system for some time to come, but it must be remembered that the fire protection will continually grow less efficient, not only because of the aging of the pipes, but because the water for domestic purposes, which must be furnished to some extent even during fires, will, with the growth of the town, become a greater and greater portion of the entire flow in the pipe system, thus reducing the flow available for fire protection.

As to the quantity of water available at the proposed sources nothing can be said definitely from the information before the Department. The report of the test of the lower well would apparently indicate that this would furnish, with proper storage, sufficient water for both domestic purposes and fire purposes, for some time to come. Nothing is known as to what the projected well may yield.

It has been determined that the proposed water works system and source of supply will not be prejudicial to public health and a permit is hereby and herein granted to the Matamoras Citizens' Water Company for the installation of water works and the supply of water to the public, as projected, under the following conditions and stipulations:

FIRST: Ample facilities shall be provided by means of blow-offs placed at all low points whereby the reservoir, gravity main, distributing system and the basin at the lower well may be completely drained.

SECOND: Detail plans of the lay-out at the pumping station and of the gravity main, force main, reservoir and distributing system, showing all valves and connections, shall be filed with and approved by the Commissioner of Health before work is commenced on these respective parts of the system.

THIRD: Before the works are completed and water is furnished therefrom, a plan shall be filed with the Commissioner of Health showing the drainage area tributary to the sites of the wells and the location thereon of the wells and of all buildings and other possible sources of pollution, which plan shall be drawn to scale.

FOURTH: Before any well other than the existing one is connected with the system, there shall be filed with and approved by the Commissioner of Health, a report, and if required, a plan of such additional well or wells indicating the construction of the same and the strata pierced thereby.

FIFTH: It is the purpose of the Department to obtain samples of water for analysis from the various parts of the system from time to time, and the water company shall render such assistance in carrying out this idea as may be necesssary, and shall make such alterations in the system and source of supply as the Commissioner of Health may suggest or approve or demand in the interests of the public health, to the end that the water supplied by said company through its system of water works shall not be prejudicial to public health.

SIXTH: Daily records of the operation of the work shall be properly kept on blank forms to be suggested by this Department, and copies thereof shall be furnished to the Commissioner of Health. Monthly inspections of occupied estates on the areas tributary to the valley above the sources of supply herein approved shall be made by the water company, the sanitary conditions noted and the results reported to the Commissioner of Health.

SEVENTH: It is stipulated that this permit is issued under the condition that all laws governing or regulating the business in which the company purposes to engage shall be complied with.

Harrisburg, Pa., June 12, 1908.

MECHANICSBURG, CUMBERLAND COUNTY.

Mechanicsburg Gas and Water Company.

This application was made by the Mechanicsburg Gas and Water Company, and is for approval of plans for a water purification plant and for certain other improvements in connection with the obtaining of a new source of supply for the public in the charter territory of said company, under certain conditions and stipulations, which are hereinafter set forth.

It appears that on April tenth, one thousand nine hundred and six, the Commissioner of Health issued a permit to the Mechanicsburg Gas and Water Company, of the borough of Mechanicsburg, Cumberland county, Pennsylvania, to extend the water supply to the public in said borough and to obtain a new source of supply from Yellow Breeches Creek at Millers Mill. The water company did not submit detail plans of the proposed improvements at that time, the preparation of these plans being deferred pending the decision of the Commissioner of Health with respect to the new source. Among other conditions the said permit contained the following:

"That the Yellow Breeches Creek water shall be purified by a modern water filtration plant before the water or any of it shall be supplied to the inhabitants of Mechanicsburg.

"That before said plant is constructed or used detail plans of the plant and its appurtenances shall be submitted to the Commissioner of Health for his approval, and he may modify or amend said plans and approve them.

"Before construction thereof, plans of the proposed force main and reservoir, standpipe or other means or facilities for storing water shall be prepared and submitted to the Commissioner of Health for his approval, and until so approved, the same shall not be constructed.

"That detail plans of the existing reservoirs, pipes gates, drain tiles, watershed, supply main and distributing mains in Mechanicsburg shall be prepared and placed on file with the Commissioner of Health."

In compliance with the terms of this permit, the water company has prepared the plans, and they are now on file in the office of the Commissioner of Health.

The plans comprise the rebuilding of the dam across Yellow Breeches Creek at Millers Mill, the installation of pumping machinery to be driven by water power developed at the mill, the erection of a mechanical filtration plant, the building of a cast iron pumping main and the construction of a reinforced concrete distributing reservoir.

It is understood that the company is not to abandon its existing source of supply.

The new dam is to be of concrete construction and is to be built immediately below the existing wooden dam across the creek. The water will be diverted by the new dam through the existing race to the fore bay at the mill. Within the present building is to be installed one turbine water wheel which is to operate a triplex pump of the ordinary type, belt driven. This pump is to be used to raise the filtered water to the distributing reservoir on the hill toward the town. Its capacity is said to be five hundred thousand gallons per twenty-four hours.

The same turbine wheel will also operate the low service centrifugal pump, capacity four hundred gallons per minute, which is to be used to supply raw water to the subsidence tanks.

This tank is to be of reinforced concrete, circular, twenty-eight feet in diameter and twenty feet deep, provided with baffles and customary inlet and outlet weirs. The normal rate of the filter plant is five hundred thousand gallons per twenty-four hours, so that a subsidence period of four and one-half hours is afforded by the tanks proposed. This structure is to be placed outside of the

building and to rest on a foundation about level with the ground. The coagulated water will feed by gravity to the filter unit which is to be set up in one end of the present mill building. Underneath this filter is to be the clear water well.

The Water Company has contracted with the Pittsburg Filter Manufacturing Company for the construction of the filter and its appurtenances, not including the subsidence tank. The filter unit is to be fifteen feet inside diameter and eight feet in height. To be constructed of cypress and to set on I beam foundation to be furnished by the Water Company as shown on plans submitted. On these beams are to rest a tongue and grooved wooden flooring. The height of the top of the filter tank is to be on a level with the top of the concrete subsidence tank outside the building. The water is to be delivered from one to the other through a ten inch pipe. This pipe will terminate at the filter in the distributing trough extending around the inner circumference of the unit, being fourteen inches above the top of the sand layer. Here the water will stand about six inches from the top of the tank, equivalent to a depth of three feet above.

Across the floor of the filter is to be laid a heavy cast iron manifold. Laterals of heavy wrought iron pipe will be screwed into the cast iron manifold six inches on centers and extend in parallel lines to the inner circumference of the filter tank. They will be capped on the outer end. The waste and collecting screens are to be of the contractor's latest design, made of the best quality of valve metal and they are to be screwed into the laterals on six inch centers. This manifold system to the base of the screens is to be imbedded in concrete.

Across the floor of the filter, which is above the waste and collecting system above described and at right angles to the central manifold, a casting is to be laid of heavy manifold air pipe. The brass pipes are to be of the best quality of brass tubing screwed into the manifold pipe six inches on centers, and extending in parallel lines to the sides of the filter. Air is to be admitted to the filter through drilled holes one sixteenth of an inch in diameter on six inch centers on the sides of the lateral tubes. Over this system of piping is to be placed a filter of gravel to a depth of eight inches and then filter sand to a depth of thirty inches. Gravel is to be of such size that it will pass a screen having a clear mesh of five-eights of an inch and be retained on a screen having a clear mesh of three-sixteenths of an inch.

Filter sand is to be specially selected and shall contain not more than five per cent. of flat or laminated particles. It shall be of hard, silicous material that will not disintegrate and shall be practically free from loam, clay and perishable matter. Sand shall have an effective size of not less than thirty-five hundredths M.M. or more than thirty-six hundredths M.M. and shall have a uniformity coefficient of not more than one and seven-tenths. Filtered water is to be delivered from the manifold system through a six inch pipe into the filtered water basin below. No regular regulator or control is provided except that it is reported that when the clear water basin is full, a float will automatically shut off the supply of raw water to the subsidence basin. Under this arrangement it is readily apparent that the filter could be easily operated in excess of its rated capacity and since the Yellow Breeches Creek is subject to sewage pollution, a repetition of the Royersford and Spring City typhoid fever epidemic of the current year could easily occur at Mechanicsburg, owing to lack of regulation of filter rates.

For washing purposes, the filtered water from the pumping main appears to be used. The connection to the manifold system is a ten inch pipe and under the pressure available, an ample supply may be had for washing purposes. The dirty water is to be wasted to the sewer which will empty into the creek below the dam. Piping connections are so designed that the first filtered water may also be wasted if desired.

There is to be provided a rotary pressure blower, driven by water power of ample capacity for properly cleaning the filter with air.

The chemical tanks are to be set up on the second floor of the present mill. Each is to be forty-eight inches in diameter and forty-two inches high, built of wood, equipped with dissolving boxes with suitable connection and spraying devices. The flow of the chemical, which under ordinary circumstances is to be sulphate of alumina, is to be regulated by means of an orifice box consisting of a small tank constructed of wood and equipped with a float for maintaining a consistent head and a finely graduated distributing orifice for feeding the solution at the proper rate to the raw water. The water supplied to the solution tank is to be taken off from the pumping main. The solutions are to be admitted to the raw water at the inlet to the sedimentation tank.

The contractor agrees from one year from the date of the completion of the filter plant, that the same, (subject to the condition that the plan shall be operated in accordance with the company's instructions, and that a suitable quanity and quality of coagulant will be used) shall be capable of filtering an average of not less than five hundred thousand gallons of water in twenty-four hours and that the filtered water shall be bright, clear and practically free from turbidity, discoloration and matter in suspension. It shall show a removal of ninety-seven per cent. of bacteria when the raw water contains three thousand or more p r c.c.

The filtered water basin is to be built by the Water Company. Underneath the end of the present mill, excavations are to be made and a reinforced concrete basin eleven feet deep, twenty-four feet nine inches wide and thirty-three feet long to be built. This length is provided in order to admit of the installation of an additional filter unit over the basin in the future. The piping is all arranged with this in view. At a little more cost, the flooring and covering of this clear water basin could be made water tight. As before stated, a wooden floor is now contemplated. Concrete flooring should be provided. This would obviate any possible danger of pollution of the filtered water in the basin.

The storage of filtered water in this basin is for purposes of pumping only. The suction pipe of the pump is to extend into this basin. The real storage of filtered water is to be obtained in the distributing reservoir on the hill.

The plan submitted by the petitioners shows the location of the proposed distributing reservoirs to the south of Mechanicsburg near one of the present reservoirs of the company. The elevation of high water is to be five hundred and fifty in this basin or one hundred feet above ninety-four per cent. of the area of Mechanicsburg borough.

This storage reservoir is to be built in circular form, two hundred and eleven feet in diameter at the top and one hundred and sixty feet in diameter at the bottom, seventeen feet deep and holding, when full, three million gallons. The sides and bottom of the dividing wall through the center are to be built of reinforced concrete. The water is to be delivered into and taken out at the bottom of each half of the reservoir. From the same point that the water is admitted and taken out, there is also provided an eight inch wash-out pipe, by means of which either section of the basin can be drained.

It should be observed that there will be no circulation whatsoever by this method of introduction and taking out of the water from the reservoir except that which may occur from natural causes in the basin. It has been found that circulation of filtered water in open basins such as the one provided for in the plans, exerts a marked influence in preventing the growth of organisms which deteriorate the quality of stored filtered water. It will be to the advantage of the water company to modify the plans of the inlet so as to produce the maximum current in each section of the distributing reservoir.

The Water Company purposes to lay a ten inch force main from the pumping station to the distributing reservoir. A profile of this line has not been submitted and the Department is not informed whether blow-outs and drainage facilities are afforded or not.

It has been determined that the proposed improvements will not be prejudicial to the public health and a permit is hereby and herein granted therefor under the following conditions and stipulations:

FIRST: That on or before January first, nineteen hundred and nine, the Water Company shall file detail plans of the existing reservoirs, pipes, gates, drain tiles and watershed and supply main of the existing water works system now used to supply water to the public in Mechanicsburg, in the office of the Commissioner of Health. At the close of each season's work the water company shall file in the office of the State Department of Health, a plan of the water pipes laid in the streets of the borough during that year together with any other information in connection therewith that may be required, in order that the Commissioner of Health may always be in formed of the extent of the water works system and the public use thereof.

SECOND: The filter plant shall be operated for one year after installation under the direction of the expert who designed it or some other competent expert. A full report of the initial test of the filter plant shall be submitted to the Commissioner of Health and thereafter the Water Company shall assist the State Department of Health in making such tests of the plant from time to time as may be desirable.

THIRD: Weekly reports of the operation of the water works system and purification plant shall be kept on blank forms satisfactory to the Department of Health and copies thereof shall be filed with the said Department. If at any time in the opinion of the Commissioner of Health, the water works system or any part thereof of any water furnished thereby has become prejudicial to public health or insufficient or defective, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

FOURTH: The Water Company shall provide for the installation of a rate control at the filter plant and such a device of approved pattern shall be installed and ready for use at the time that the filter unit is put in commission.

FIFTH: The Water Company shall construct a reinforced concrete, water-tight floor and roof over the clear water basin.

When the improvements herein approved are completed, the Water Company shall file a complete set of plans of the structures and changes in the office of the Commissioner of Health. Ample facilities for draining the force main shall be provided, and the company's attention is specially called to the desirability of carrying out the suggestions hereinbefore made with respect to circulation of water in the distributing reservoirs. It will be cheaper for the company to do this now than at a later date.

Harrisburg, Pa., September 25th, 1908.

MINERSVILLE, SCHUYLKILL COUNTY.

Minersville Water Company.

This application was made by the Minersville Water Company of Minersville Borough, Schuylkill County, Pennsylvania, and is for permission to construct a reservoir for impounding an additional water supply to the public in said borough.

It appears that Minersville had in nineteen hundred a population of forty-eight hundred and fifteen and the present population is reported to be approximately six thousand. This borough is situated about four miles west of Pottsville, the seat of Schuylkill County. The men and boys are generally employed in and about the collieries in the vicinity. A number of the girls are employed in factories and the laundry in the town. The people are mostly of foreign birth.

The borough is situated in the midst of the coal measures on the west bank of the West Branch of the Schuylkill River. A small stream called Wolf Creek rising in Mine Hill to the north, flows down through the center of the town and is used as a drain for two collieries and for the village itself. On either side of this creek in the borough there are high hills upon which and in the valley between is located the built-up part of Minersville. A part of Wolf's Creek is arched over and into it the combined sewers of the municipality empty and also private sewers. Wolf Creek drains a very narrow and steep watershed and during storms the flow has a scouring effect which washes out all accumulations in the culvert onto the flats in the lower part of the borough. There is no reliable data at hand now in the office of the Department, showing the extent of public use of the sewer system but it is known that sewers are very generally laid throughout the streets of the town. There are a number of cesspools and many privies in the borough and a dozen or more private wells, so it is reported. People very generally take water from the Minersville Water Company.

The Minersville Water Company was chartered by Act of Assembly, April thirteenth, eighteen hundred and fifty-five; Letters Patent being granted on March twenty-eighth, eighteen hundred and fifty-seven, for the object of conveying water to the borough of Minersville. This is the only corporation authorized to supply the borough of Minersville.

It is reported that the first works were built about eighteen hundred and fifty-eight and that parts were reconstructed in eighteen hundred and ninety. At present the borough and parts of the townships of Cass and New Castle are supplied by the Minersville Water Company. By what authority the supply of water to the public outside of the borough is undertaken by the Minersville Water Company, is not known to the State Department of Health. The Company reports that the poulation supplied with water outside of Minersville borough is in the neighborhood of three thousand.

The system is a high service gravity supply, affording a pressure reaching from sixty-five to one hundred and fifty pounds per square inch.

The company has not submitted any plans of its water pipe system in the borough showing the sizes, location of valves and draining facilities.

The source is obtained from three streams located in Schuylkill County in Cass Township and north of Mine Hill, namely Dyers, Wagners and Wheelers Creek. These streams are all typical fresh water mountain brooks with no habitation whatever on their watersheds above the reservoir from which the supply is taken.

Dyers Run is the largest of the three brooks. It has a watershed of five square miles. This stream heads in springs on the top of Broad Mountain four miles from its mouth. The growth on its watershed of four square miles consists of shrubs, bushes and some second growth timber. The soil is mostly the disintegrated conglomerate, together with some clay and loam. At one time the Mine Hill and Schuylkill Haven Railroad (Philadelphia and Reading Railway) between Minersville and Gordon Plane passed over this shed, but the road is now abandoned and the tracks torn up. The road bed is not used for purposes of traffic. The largest reservoir of the system is located on this stream about three and three-tenth miles from the borough and at an elevation of eleven hundred and forty feet mean sea level. It consists of a dam thrown across a gully and is said to have a capacity of about nine million gallons. The dam is a dry stone masonry dam with a clay puddle cord and a puddle face, from it leads a fourteen inch supply main. The vegetation and organic growth was cleaned off the site before water was allowed to impound. There are no present indications that such growth exists. There is a caretaker at this reservoir.

The second reservoir in size is situated at Wagners Creek, a small stream having a watershed above the dam of seven-tenth square miles. This stream is directly east of Dyers Run, but in a small valley of Broad Mountain and the general conditions relative to it are the same as those on Dyers Run. The impounding reservoir is of same kind and constructed like the others and is distant about two and nine-tenths miles from Minersville. It has a capacity of approximately six hundred thousand gallons. The water discharges into an eight inch pipe line laid for about a half mile parallel to the stream and there connects to the fourteen inch line from the Dyers Run reservoir to Minersville.

Wheelers Creek parallels and is immediately east of Wagner's Creek. It is a small stream and upon it the third reservoir of the system is located. This structure is of the same class as the others and has a storage capacity of three hundred thousand gallons. The watershed above is estimated to be three tenths of a square mile in area. An eight inch supply main is laid down the valley about one-half mile to the fourteen inch supply main to the Dyers Run reservoir.

The last two named reservoirs are at a higher elevation than the larger one. They are held as an auxiliary supply of minor importance.

The west branch of the Schuylkill River above Minersville passing up stream follows the course nearly northerly for a distance of about two miles and thence it turns at right angles around the end of Mine Hill and its course is due west into the Broad Mountains, a distance of about four miles, where are its headwaters. Dyers Run and Wagners and Wheelers Creeks flow southerly and empty into the west branch. The main fourteen inch supply pipe from Dyers Run reservoir is laid down the valley of the west branch of the Schuylkill to Oak Hill colliery near Minersville borough line. Here the fourteen inch main branches into two eight inch lines, both of which are extended to the borough of Minersville and parts of Cass and New Castle Townships. New Castle Township lies east of Cass Township and east of the west branch of the Schuylkill River. Norwegia Township is east of the river opposite Minersville and for some distance north of it. The said fourteen inch gravity supply main in following down the valley passes out of Cass Township through a small portion of New Castle Township, but it is not known to pass through any of the Norwegian Township territory. Off of this line in Cass Township and New Castle Township there are branch pipes used to supply water to the public and to Lytle, Pine Hill, Oak Hill and West Pine Knob coal collieries. From the information submitted by the Minersville Water Company, it is not known whether such company owns these branch supply pipes.

On July second, eighteen hundred and ninety, the Crystal Water Company was incorporated to supply water to the public in Cass Township, Schuylkill County. It appears that this corporation, which is controlled by the Philadelphia and Reading Coal and Iron Company, has an impounding reservoir of considerable size on a stream in the western part of Cass Township, from which it supplies water to the public and to collieries in that portion of said township and to the Otto Water Company in Reilly Township to the west and to Deep Water Company in Branch Township, to the south, said county. In the Crystal Water Company's chartered territory is located the Lytle colliery of the Susquehanna Coal Company and the plans filed by said water company in the office of the Commissioner of Health show a pipe line laid to said colliery. However, the Minersville Water Company and also the officers of the said Lytle colliery both state that water is furnished and sold by the Minersville Water Company to the Lytle Coal Company at its said colliery which is in Cass Township, north of and about one and one-half miles distant from Minersville borough. It also appears, as above stated, that the Minersville Water Company furnishes water to the Pine Hill colliery, located in the same neighborhood and operated by Sturgis and company. Furthermore, the said water company supplies water to the Oak Hill colliery of Leisenring, Writer and Company, located in Cass Township, at the end of the fourteen inch supply pipe above mentioned. It also furnishes water to the West Pine Knob colliery of the Philadelphia and Reading Coal and Iron Company, located in Cass Township, near the mouth of Dyers Run.

On December seventeenth, eighteen hundred and ninety, the Forestville Water Company of Minersville was chartered to exist for twenty years to supply water to the public in Cass Township, Schuylkill County. The pipe lines of this corporation was laid to supply the said Lytle colliery and miners' houses in the neighborhood. Water is furnished by the said Minersville Water Company and by the said Crystal Water Company. It is estimated that about seven hundred and fifty people rely upon the Forestville Water Company for their drinking water.

The water works of the Forestville Water Company comprise only the pipe lines, pump and tanks at the colliery and the settlement in the vicinity. No detail plans have been submitted.

The petitioner proposes to build a new dam and reservoir. The following is a copy of the application:

"On behalf of the Minersville Water Company, a company incorporated under the Act of the General Assembly of the Commonwealth of Pennsylvania, P. L. six hundred and thirty-nine, approved the thirteenth day of April, eighteen hundred and fifty-five, I make application for a permit authorizing the said company to construct a reservoir for the purpose of impounding an additional water supply from the waters of Dyers Run in Cass Township, Schuylkill County, Pennsylvania, about nine thousand feet on said stream, above the location of the company's present impounding reservoir thereon, and also to do whatever is necessary to protect the water of the said stream from pollution and diminution.

"I enclose you herewith a certified blue print copy of the preliminary plan of the breast of the proposed dam, and also a certified blue print copy of a preliminary plan of the proposed reservoir, the location of which will be found upon the plans and surveys of the said company's water works, etc., already on file in your office, in compliance with the Act of April twenty-second, nineteen hundred and five."

The object of the dam is to store water to be used during droughts only. It will be an earth and rock filled structure, having a concrete core wall four feet thick with puddle on the inner slope. The design will provide for a forty-five foot structure in the future but for the present the dam is to be erected twenty feet only to the crest. This will give a storage for the present of about twenty-eight million gallons increased to fifty million gallons for the higher elevation. The watershed above the site of the dam has an area of about one and one-half square miles. The fall in the stream between the proposed reservoir and the old one is three hundred and forty feet and the intervening territory is a narrow, rock valley a few hundred feet wide and uninhabited. The plan is to open the valves in the new reservoir and permit the impounded water to flow down the run to the lower reservoir.

The watersheds of the Minersville Water Company's supply being uninhabited are free from permanent sources of pollution. The only danger, therefore, to contamination of the supply, is that of accidental pollution. The water gives satisfaction to the consumers and there seems to be no reason why the desired permit should not be granted to the Minersville Water Company. On the day of the Department's inspection at the site of the new dam, trees and stumps were being cleared and the organic matter on the land to be flooded was being removed to some extent. The total area to be flooded is not known nor the extent of shallow flowage, except that the preliminary sketch shows a fairly good depth of flowage for the higher dam. In case of deterioration of the quality of water by vegetable organisms, such remedies as are customary would have to be applied by the water company to remove tastes and odors from the water. The aeration of the water in the mile and three-quarters course between the two dams would operate naturally to benefit the water, and it would seem reasonable to wait until the deterioration of water occurs, if ever, before determining the best remedies; but the water company should expect to be advised and required to apply remedies whenever needed.

The supply of water to the public outside of its chartered territory is a matter which cannot receive the approval of the Commissioner of Health until the rights so to supply water beyond the limits of Minersville borough shall have been acquired by said company.

It has been determined that the water works system and source of supply and the proposed new source of supply and extension of water pipes within the limits of Minersville borough will not be prejudicial to public health and the same is hereby and herein approved and a permit granted therefor under the following conditions and stipulations:

FIRST: On or before the first day of January, nineteen hundred and nine, the water company shall prepare a detail plan of the water pipes in the borough showing their sizes, location of gates, blow-offs and drainage facilities and the same with respect to the pipes belonging to the company outside of the borough limits, also detail plans and elevations of the reservoirs, dams, gates and drainage facilities thereof belonging to the company and file the same in the office of the Commissioner of Health. Thereafter at the close of each season's work, plans shall be filed by the said company of the water pipes laid during the year, in the office of the Commissioner of Health, together with any other information in connection therewith that may be required, to the end that the State Department of Health may always be informed of the extent of the water works and the use thereof.

SECOND: On or before January first, nineteen hundred and nine, the water company shall file with the Commissioner of Health, detail plans of the new reservoir and dam.

THIRD: If at any time in the opinion of the Commissioner of Health, the water works system or any part thereof or the source of supply shall have become prejudicial to the public health, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

FOURTH: If any lumber operations should be undertaken on the watershed or any habitation or source of pollution be established on the watershed at any time, the water company shall immediately notify the Commissioner of Health thereof and co-operate with the State Department of Health in enforcement of sanitary regulations to safeguard the purity of the waters used by said company as a source of supply to the public.

FIFTH: If the public health shall require it, the State Board of Health shall establish rules and regulations for the operation of the waters works system and the water company shall be bound in accepting this permit to abide by and observe such rules and regulations in so far as they shall relate to public health matters.

SIXTH: Approval by the Commissioner of Health of the supply by the Minersville Water Company to the public in any other territory except that prescribed by its charter, is herein withheld and denied. However, if the company shall first obtain a legal right to supply water in the townships through which its main supply pipes are located, the Commissioner of Health may thereupon grant an approval for such supply to the public.

Harrisburg, Pa., July 23rd, 1908.

MORGANZA, WASHINGTON COUNTY.

Pennsylvania Reform School.

This application was made by the Board of Managers of the Pennsylvania Reform School, located at Morganza, Cecil Township, Washington County, and is for approval of plans for water filters, improvements to the water works system and for a new impounding reservoir.

It appears that the Pennsylvania Reform School is a State Institution for the care and education of incorrigible children up to the age of twenty-one years. The school was established in eighteen hundred and fifty-two on the site of the present penitentiary in Pittsburg. In eighteen hundred and seventy-two, it was moved in its entirety to the present site at Morganza. The institution to-day comprises a main building, four cottages for boys and a large building for the care of the girl pupils, a public school building for boys, three shop buildings in which trades are taught to the boys, a hospital and farm buildings. There are in process of erection two cottages, one for boys and one for girls, and a large gymnasium and a power house. They are all situated on a five hundred and twelve acre tract of land located in Cecil Township, Washington County, north and west of Chartiers Creek, which flows in a general south-easterly direction by the property. This creek makes a large bend in its course so that it forms the western boundary of the southerly portion of the property and through this part the Chartiers Valley Division of the Pittsburgh, Cincinnati, Chicago and St. Louis Railroad extends. Morganza Station is on the land occupied by the state buildings.

The Administration Building and four cottages are directly back from the station on a bluff which is one hundred feet or so above the creek valley and the other buildings are situated back from this bluff on rising ground which is laid out in regular plots and drives for the prospective cottage development of the institution.

Near the northern boundary of the land reserved for future cottages is a water course locally known as Morganza Run which rises north in the township near the village of Bishop and pursues a generally southerly direction, a distance of about two and a half miles, to Chartiers Creek. The latter seventeen hundred feet of the course follows closely the northern boundary of the State property.

The valley of this run and the entire watershed is under cultivation.

The population of the institution, including officers, numbers about five hundred and fifty. It is estimated that the average daily water consumption approximates one hundred and twenty-five thousand gallons.

On the institution grounds in the northern part, a small intake dam on Morganza Run was erected to divert the water of the stream into the water pipe system of the institution and this source was the first supply. Later, owing to the inadequacy of the supply, an intake dam and pumping station was erected near the banks of Chartiers Creek and the major portion of the supply was drawn from the creek. Subsequently, owing to coal mine operations and the pollution of the waters by mine drainage and sewage, the creek supply was abandoned, except for emergency uses, and Morganza Run was again resorted to. A small intake dam of timber construction was built on the run five hundred feet below the site of the original dam and the water was conveyed by a pipe to an artificial pond on the bank of the stream about five hundred feet distant. This basin was an earth structure, partly excavated and partly held in embankment, being about one hundred and forty feet long by eighty wide, affording a three foot depth of water. Its use was that of a pump well and ice pond. From this basin the water was pumped into a distributing reservoir on the hill in the northern part of the institution grounds elevated about one hundred and eighty feet above the main building.

At the present time the institution's water supply is derived from three sources; first, raw water from Morganza Run for general inferior uses; second, from springs for drinking purposes; and third, from Chartiers Creek and a drilled well at the creek pump house for inferior uses.

The main supply is derived from the run and is diverted by means of a dam and the ten inch tile pipe to the open basin and pump well above described. The water is raised by means of a horizontal, duplex pumping engine of five hundred gallons capacity per minute through about a half mile of six inch cast iron force main to the distributing reservoir located on the hill north of the institution.

The distributing reservoirs are two in number, each seventeen feet deep and thirty-six feet by fifty-one feet in plan, vertical walls brick lined, cement bottom, having a combined capacity, at a depth of fifteen feet of water, of four hundred and thirteen thousand gallons. There are facilities afforded at the bottom of these reservoirs for drainage. The pumping engine is operated daily for a few hours until the high water mark is reached.

From these reservoirs the water is supplied by gravity to all the buildings, including the barns, stables and farm house, and is used for flushing, sprinkling, bathing, stock, and other general purposes, except for drinking. One of the rules of the institution forbids the use for drinking of the faucet supply; but it has been found difficult to entirely prevent the use for this purpose.

There is no plan in existence of the distributing pipe system. There appears to be a six inch and eight inch supply line from the hill reservoir. About the grounds at convenient points fire hydrants have been erected. It is reported that most of

the distributing pipe is four inches in diameter. The value of the state buildings and the necessity for adequate fire protection warrants the obtaining of accurate knowledge of the exact diameters of the water pipe.

It is possible, by means of valves and connections, to pump Morganza Run Water directly into the distributing system, by-passing the reservoirs, so it is reported. The facts as to this by-passing should also be ascertained and accurately indicated on the plans.

For drinking purposes, water is obtained from two or three springs located on the ground. The principal spring is on the hillside in front of the administration building and about half way distant between said building and the railroad station. The formation is limestone and originally there was a small ravine in which the spring gushed forth from the limestone. Rocks were thrown in here and carefully piled together and then the ravine was filled with earth up to the general level of the lawn as it may be seen to-day. A two inch pipe extends from the underground spring down hill towards the railroad and terminates in a galvanized iron tank about eighteen inches in diameter and three feet high, resting on a brick foundation slightly above the surface of the ground. There is a faucet near the bottom of this tank from which water is drawn for use. Formerly a water wagon hauled all the drinking water to the main buildings, supplemented by family bucket brigades for fresh water supply to the cottages for table use. This system is maintained in part at the present time, but generally speaking the girls' buildings are now supplied by a pumping system. The overflow from the iron tank is piped to a brick, cement lined, storage basin of about fifty barrels capacity, located near the railroad and the old power house, where there is a small pumping engine which raises the water through a two inch force main to a second brick, cement lined reservoir of the same size, located in the ground back of the Administration Building and near the group of shops. This structure is elevated sufficiently high to furnish a gravity flow under low pressure to the ground floor or basement of the Administration Building and four cottages adjacent thereto.

Another important spring is in the grove on the slope towards Chartiers Creek northeast of the shops. The water flows from limestone rock through an inch pipe and falls free into an artificial stone basin in which there is no storage. The water is obtained here by putting receptacles under the end of the pipe.

The next spring of importance is in the immediate vicinity of one of the new cottages being erected and within seventy-five feet of the main fifteen inch sewer of the institution. It is reported that this spring which comes from the limestone is in what was formerly a ravine, which has been filled in a manner similar to that described with respect to the first spring herein mentioned. A six inch pipe about two hundred and fifty feet long conveys this water to an open, brick lined basin about three feet in diameter and flush with the surface of the ground. Surface water contamination is possible here. It is always full of water. The overflow is into a nearby lily pond. Water has been occasionally taken from this well for drinking purposes, more especially by the families in the three nearest cottages.

During the latter part of the current season, a spring at the farm house has been drawn upon. It is in a spring house, the water flowing from the bank out of the limestone.

At the Chartiers Creek pump house there is a drilled well, deep and connected up to the pump. The machinery is old. The water raised from this well has an odor and disagreeable taste and the supply is limited. At the pump house there is a seventy-five thousand gallon, circular, brick pump well, into which the deep-seated water is delivered and from whence, by a second pumping engine, the water is forced into the distributing system of the institution. This latter pump may also draw water directly from the creek and deliver it into the system. Whenever the Morganza Run supply is insufficient, the driven well is resorted to and finally raw water is used. Any surplus pumpage overflows from the pipes into the distributing reservoirs on the hill.

On the hill adjacent to the twin distributing reservoirs is a large reservoir approximately one hundred feet square, with sloping sides and thirteen and a half feet deep. It is brick-lined. This structure is not water tight and hence is not in use. The capacity on a twelve foot basis is slightly in excess of five hundred thousand gallons.

The watershed of Morganza Run above the intake dam has an area of about two square miles and on it there are twelve dwellings, all occupied but one. Nine of the estates are farms. There are quite a number of oil producing wells on the watershed and new wells are being drilled from time to time. A detailed map of the drainage area and occupation thereof is now being prepared by the Board of Managers and will be filed in the office of the State Department of Health.

The institution has witnessed considerable typhoid fever during its thirty-two years' existence at Morganza. Three times it has shown in epidemic form. The attending physician reports seventy cases for eighteen hundred and ninety-eight, sixty cases for nineteen hundred and three, nine cases for nineteen hundred and seven and forty cases for the current year. With a few cases occurring in other years, the total has been nearly two hundred cases during the last ten years, the cause of which has never been determined.

On July twelfth, eighteen hundred and ninety-eight, the first case appeared in Cottage D, where the boys average fifteen years of age. In the following table the date of onset of each case and the location of cottage in which the patient resided are shown:

LOCATION OF COTTAGES.

1908. Date of Onset,	No. of Cases.	Cottages.	D	F	C	B	A	E

During the time covered by the table and the outbreak, Morganza Run water was generally supplied to the buildings and the two principal springs were in general use for drinking purposes. It will be noticed that no cases occurred in the girls' cottages or among adults, so the infection was not likely to have come from any food or water supply in general use. The milk supply was run down and found to be pure. If the conclusion be correct, the Morganza Run and the two principal springs are relieved from suspicion and there remains Lily Spring to examine.

It will be noted that the cases occurred in the cottages supplied by drinking water partly from Lily Spring. Cottage E is nearest the spring and in it there were thirteen cases and there were thirteen cases in Cottage A, the next nearest building. There were eleven cases in Cottage B, which is the third from Lily Spring. The other three cases were in the buildings further removed. It appears that the epidemic was confined to the users of Lily Spring, because in Cottages E, A and B the boys had daily access and drew water from Lily Spring as previously described. The dates of onset indicate a weakened infection and a continual recurrence to the poison. It is such an outbreak as would be expected where a number of families use infected water from a spring week in and week out. The type of the disease was the mildest form. There was one death only. The investigator would naturally look for a constantly polluted source of non-virulent kind and it is believed that the Department has discovered such source of infection in the sewer previously mentioned and distant seventy-five feet from the spring.

Every occupied estate on the watershed was visited. No typhoid fever was discovered. During the previous year there was one case on the shed.

The first case, on July twelfth, was located in Cottage D at the end of the main sewer line. During the first week of the August outbreak the main sewer was opened near Lily Spring by the superintendent and the structure was found to be in a leaky condition and immediately Lily Spring was put out of commission permanently by cementing up the well. Its use had been prohibited on August second, on suspicion. During the middle of the month, while excavations were being made for the basement of one of the new cottages over the main sewer, distant about two hundred and fifty feet from the spring, it was discovered that every joint was broken in a distance of about eighty feet, indicating that a similar condition may obtain throughout the entire sewer line. Closer inspection revealed that the joints on the bottom had never been properly cemented. When it is recalled that such a main sewer passes fifteen feet above and seventy-five feet distant from Lily Spring and that the structure is porous and partly filled earth,

the connection between the infection discharged into the sewer line from Cottage D on and prior to July twelfth and the subsequent infection of Lily Spring followed by the daily onset as reported can be understood.

A hole was dug in the porous soil near the sewer and a salt test was applied, showing that twelve hours' time would permit the passage of the salt water into the spring. Hence sewage from the sewer pipe could pass through in this time.

It was concluded by the institution and State authorities that an improved sewerage system and water works system was demanded at the institution.

The plans now submitted provide for the construction of a dam to be located a few hundred feet above the present intake on Morganza Run, entirely on the property of the Institution. This dam is to be an earthen enbankment, concrete core wall structure, twenty-five feet above the bed of the stream and length over all three hundred feet. Across the top of the dam is to be a roadway twelve feet wide. The top of the core wall will be flush with the surface of the roadway. Normal high water in the reservoir will be four feet below. The sides of the dam will slope uniformly on either side two feet horizontal to every vertical foot and the slope on the reservoir side is to be riprapped from the top of the dam to an elevation fourteen feet lower to prevent erosion by wind and ice action. Flood run-offs, and waste water are to be carried around the dam through a spillway channel excavated in the hillside. The entrance to this spillway is a semi-circular, concrete weir, elevation nine hundred and fifty-five, which fixes the height of normal water in the reservoir. The channel is thirty-one feet wide on the top and fifteen feet on the bottom. The bed and the vertical side two feet high are to be built of concrete and from these vertical sides the slopes are to be stone paved. The total vertical height from the bed of the spillway is six feet. The flood discharge capacity is based on a run-off of eight hundred cubic feet per second.

A line of perforated pipe along or near the bottom of the core wall inside and a few feet above the toe of the down stream slope of the dam is connected up to a well for the collection of seepage water. The core wall is to be imbedded in rock six feet below the channel of the run and along the extreme toe of the outer slope is a layer to a depth of about two feet of broken stone.

This dam will impound over twenty million gallons, equivalent to five months' supply to the institution at the present rate of consumption. The area flooded will cover about eight acres and the greatest depth of the water will be twenty feet. At the upper end of the basin, which is about twelve hundred feet long and an average of about three hundred feet wide, there is some shallow flowage, but not much. The site is grass land. It is proposed to strip the shores of the reservoir comprising that portion submerged at high water to a depth of four feet. Loam and sub-soil will be partly used in facing the lower slope of the dam. Outside of this stripping the flooded area is to remain as it now is; but at the site of the dam, of course, all material is to be removed to solid earth. In fact, this has been done and the structure has been partly built. An appropriation of twenty-five hundred dollars was made by the Legislature of nineteen hundred and seven for the land. The work is being performed by the pupils and it is intended to complete the work with this labor. An added appropriation will be needed for material.

Provision for draining the reservoir consists of a small concrete intake on the bottom above the dam, ten inch cast iron pipe protected by a screen extending through the bottom of the dam to an outlet concrete chamber down stream. The gate on this pipe line is near the outlet. If the water in the lower layer of the reservoir should be used at any time, this blow-off arrangement by means of a connection can deliver the water to the main supply pipe to the institution.

The eight inch cast iron main supply pipe begins at a circular concrete basin called the aerator, located nearly below the dam. This structure is twenty feet in diameter, four feet deep and in the centre there is a vertical pipe, at the top of which there is affixed a nozzle to spray the water. This riser pipe is connected by two six inch feed pipes leading to the reservoir, one of these pipes has its end submerged two and a half feet below the normal surface of the reservoir water and the other pipe is submerged five feet lower. The gates on this feed pipe are near the aerator.

Owing to the extensive demands on institutional labor, it is not practicable to build the proposed filter plant except by contract, therefore, an appropriation must be secured.

The State Department of Health has made inspections of the estates on the watershed and will assist the management of the Reform School in maintaining a patrol and sanitary regulations. Even then the supply would not be absolutely safe. Filtration is necessary. Usually the stream is a clear one. Its turbid periods are of short duration.

The proposed filtration plant is to receive the water by gravity from the new impounding reservoir. It is to be located near the existing pump house on the banks of the run. It is designed to purify three hundred thousand gallons of water daily, at a net rate of between one and a half and two million gallons per acre per day. This conservative rate has been adopted because of the turbidities of the water. The slow sand method is proposed because it is peculiarly adapted for this institution. The reason is that the operations may be entrusted to selected pupils, because of simplicity. The operations of mechanical filters would, it is thought,

involve skilled attention, necessitating an additional permanent expense which may be avoided. Filters are to be in duplicate, each seventy feet by sixty feet interior dimensions of filtering area on either side of a central gallery housed over, which gallery is fifteen feet. The water is to be delivered by gravity into a control chamber in the forward part of the building. Into and out of this chamber lead the pipes carrying the influent, effluent and waste water. The regulating valves and indicating apparatus are located here. Beyond this chamber the gallery is divided by longitudinal walls, which walls form the main wall of each filter. There is an extension of the filtering surface to this wall so that from the platform above may be seen the surface of the water on the filters. Adjacent to the control chamber is a plat form in each filter unit level with the surface of the sand from which an incline rises. The further end of the gallery is to be utilized as the sand washing room. This floor is concrete. Here will be set up the ordinary machinery for sand washing with jet from reservoir pressure. The waste water will be delivered to the drain, an eight inch cast iron pipe, leading to and terminating in the main drain at the control chamber. This main drain is to take the overflow, if any, from the surface of the filters and also for draining the filters, there being a by-pass connection between the drain and the main effluent pipe. This main drain has its outlet into the run near the pump house.

The concrete floor of each filter unit slopes to the middle where there is a ten inch vitrified pipe laid below the floor into which half channel six inch tile pipe, laid in parallel rows ten feet on centers, will deliver the filtered water. These underdrains are to be surrounded in the customary manner by coarse filtering material graded and over all is to be placed four feet ten inches, average depth, of filter sand. This material is to be water washed and graded to a uniform size suitable for the purpose. The high water mark is to be four feet above the sand level or at elevation nine thousand three hundred and fifty-five, nineteen and a half feet below the normal level in the impounding reservoir. Hence it may be seen that there is sufficient fall for the delivery by gravity to the filter plant of run water, even if the reservoir supply were depleted or drained for any purpose.

The scraping of the filters is to be done by hand by institutional labor. The sedimentation is so great in the impounding reservoir that precipitants may be avoided. Furthermore, the storage of filtered water is so great that the filter operations may be suspended during times of great turbidities.

The filters are to be covered with a concrete roof supporting two feet of soil.

A clear water basin, fifty by forty feet in plan, of concrete construction, bottom, sides and roof, ten feet deep to flow line, holding one hundred and fifty thousand gallons or twelve hours' flow, based on the normal capacity of the filters, is to be located adjacent to the pump house. Connected with the present pumping engine there is to be an eight inch suction pipe terminating in the clear water basin at a point diagonally opposite the inlet.

It is purposed to make the large distributing reservoir on the hill watertight and to cover it and the adjacent twin reservoirs with a concrete roof. Proper drainage facilities and overflow arrangements are to be provided. The combined storage capacities of these three basins will be slightly under one million gallons, or a week's supply to the institution.

It is also proposed to make some changes in the distributing pipes through the ground. The plan is to provide a direct connection from the pump to the pipes leading to some of the main buildings, in order that the distributing reservoir may be cut out temporarily, if necessary, or, in case of accident, to admit of direct pumpage. The present reported by-pass is not considered suitable or sufficient.

With the proposed improvements carried out, and the watershed placed under sanitary control and the filter plant operated in a proper manner, the water supply at the Reform School should be equal to the best obtainable, provided the existing sources be absolutely abandoned.

The drilled well and Chartiers Creek supply is prejudicial to health as a water supply. Immediately on the installation of the filter plant and the successful inauguration of it, the pumping machinery at the Chartiers Creek pump house should be removed.

The Lily Spring has been abandoned. This should be followed, as soon as filtered water be introduced at the institution by the abandonment of the principal spring in front of the main building, and, meantime, the Department will make monthly bacteriological examination of the spring water on receipt of samples sent by the management of the school. This is necessary because the geological formation and relative positions of the main sewer and the spring and the probable faulty condition of the sewer introduce an element of risk involving the security of human life, which the State Department of Health and the institution management should not assume in the face of the facts. While it appears that this water has been pure, so far as is known, and it may continue on test to be found pure, nevertheless, this does not alter the proposition as stated above. Finally, it is not necessary to continue this spring in use after the filtered water shall have been introduced.

The completion of the dam should be hastened and the erection of the filter plant also. At the close of the season of nineteen hundred and nine, both improvements should be completed.

A duplicate pumping engine and steam plant should be installed at the pump house and necessary enlargements and additions in connection therewith.

It has been determined that the proposed improvements will not be prejudicial to public health and a permit is hereby and herein granted therefor, subject to the following conditions and stipulations:

FIRST: The Board of Managers shall endeavor to obtain an adequate appropriation for the erection and completion of the impounding reservoir, filtration plant, proposed changes and improvements to the distributing system, including an additional pumping outfit, in order that these improvements shall be completed by the close of the season of nineteen hundred and nine.

SECOND: The water filters shall be built under the responsible supervision of the experts who designed them, or some other expert equally competent to render the service. And the plant shall be operated for a reasonable length of time after being put in commission under the responsible direction of such an expert, in order that the efficiency of the entire plant as designed shall be obtained.

THIRD: The Board of Managers shall notify the State Department of Health when the filter plant is ready for the final test and after it shall have been determined to the satisfaction of the Commissioner of Health that the filter plant is efficient, it shall be put into commission and nothing but filtered water shall be delivered to the institution. All existing and present sources of water supply, except the filtered Morganza Run water, shall be discontinued and the pumping engines in connection therewith shall be dismantled.

FOURTH: Daily reports of the operation of the water works and filter system shall be kept on blank forms satisfactory to the State Department of Health and copies thereof shall be filed with the said Department whenever required.

FIFTH: If at any time in the opinion of the State Department of Health the water works system or any part thereof, or the water supplied thereby, shall become prejudicial to public health, then such remedial measures shall be adopted and enforced as the Department may approve or advise.

SIXTH: The Board of Managers shall maintain a sanitary patrol on the watersheds. Every occupied estate in operation shall be inspected at least once monthly, all nuisances and menaces shall be noted and promptly reported to the State Department of Health, together with prompt information as to the outbreak of any case of any infectious disease.

The suggestions relative to revision of the system of distributing pipes are especially called to the attention of the Managers, more particularly in relation to adequate fire protection.

It is, of course, understood that the distributing reservoirs and pipes will be thoroughly flushed and cleaned before the introduction of filtered water.

Plans of any alterations or extensions of the water works system as herein approved shall be filed in the office of the State Department of Health, in order that the Commissioner of Health may always be informed of the extent of the system at the institution.

Harrisburg, Pa., November 17, 1908.

MOUNT UNION, HUNTINGDON COUNTY.

Mount Union Water Company.

This application was made by the Mount Union Water Company of Mount Union, Huntingdon County, and is for permission to obtain an additional source of supply.

Mount Union Borough is a community of about three thousand, two hundred population located on the main line of the Pennsylvania Railroad along the south bank of the Juniata River and on the mountain side about twelve miles down stream from the county seat and the borough of Huntingdon. It is a thriving industrial town. The principal manufacture is silica and fire brick. There are two large concerns engaged in this business employing possibly six hundred men which have been located in the borough since nineteen hundred. Their advent has more than doubled the population. There is also a tannery. The Broad Top Railroad which comes down the valley of Aughwick Creek has its terminal station in the borough and a connection with the Pennsylvania system. A number of the railroad hands live in the village. On the flats north of the Pennsylvania Railroad and the canal (now abandoned) there are numerous dwellings where possibly a third of the inhabitants reside. The principal part of the town, however, is on the mountain side south of the railroad. Here the grades are steep and the ground is a broken, shaley, clayey structure. Dug wells are used on some of the properties for the household water supply. Some of the wells have been abandoned for this purpose and are now used as a repository for sewage. There are over five hundred old time privy vaults, many of them being shallow earth pits full to overflowing. Rain water can wash this material over the surface of the ground into the wells. There is also danger of sub-soil contamination. The risk run in drinking the water drawn from the ground in proximity to the sources of pollution is evidenced

by the typhoid fever records. It appears that during nineteen hundred and seven there were seventeen cases; during nineteen hundred and six there were forty-six cases; and in nineteen hundred and five there were at least seventy-five cases. Prior to this time if unauthenticated reports be true there were even more cases annually. The town is contemplating the installation of a public sewer system to remove the poisons away from the vicinity of the dwellings.

The Mount Union Water Company was chartered in June, eighteen hundred and ninety-nine for the purpose of supplying water to the public in the borough. It entered into contract with the local authorities during the following year and built the works at that time.

The existing water works system comprises a collecting reservoir for ground water, a gravity supply main to the town and a distributing pipe system in the village.

The source is a number of springs on the southern end of Jacks Mountain north of the Juniata River. Part way down the mountain side, there is a cemented wall across a gully filled up with broken gannister rock. The wall impounds possibly fifty thousand gallons of water which flows down through the rock spaces from the springs above. The flow line at the dam is about level with the highest occupied ground in the borough or approximately two hundred feet above the business section of the borough. The watershed is uninhabited and thickly wooded. There is no source of pollution on it. From the dam a six inch cast iron main extends easterly down the mountain side and across the river channel and along the railroad a distance of about two miles to town. The village streets are quite thoroughly piped and fire hydrants have been erected throughout the town. It is estimated that five-sixths of the population use the supply. The Broad Top Railroad Company, the tannery and the Harbison-Walker Refractories Company are liberal consumers of water. The average daily consumption is reported to be two hundred thousand gallons and the maximum three hundred thousand gallons. During wet weather Jacks Spring, the main source, furnishes an ample supply but in dry weather the company is forced to economize in the supply of water.

The community is in a thriving condition and its principal industries being quite stable assure some future growth. An ample supply of water for all seasons of the year and for increased consumption is demanded. The company purposes to obtain the new supply in addition to the present source from two tributaries of Furnace Run. There are two mountain brooks each having their source in a spring on the eastern slope in Jacks Mountain opposite the borough across which, above the old Lewistown Huntingdon Turnpike, now little used, on which it is proposed to build a small masonry intake dam at an elevation to be definitely fixed by the engineer on the level with the Jacks Spring reservoir. It may be three miles above these proposed dams to the mountain summit, an extent of barren rock and occasional forested area. There is no source of pollution on it.

From these intakes it is proposed to lay a six inch main down the run and across the river to the town. Where the pipe crosses the river it is to be eight inches in diameter.

The water company is not in possession of a plan of its water works system and this information should be filed in the Department's office. It would appear that the present and the additional source of supply are exceptionally good ones. Undoubtedly storage of water in the borough would be a marked improvement more especially since the service is supposed to furnish fire protection. The next six inch main will have an approximate length of one mile north of the river.

It has been determined that the water-works system and the proposed source of supply will not be prejudicial to the public health and the same are hereby and herein approved and a permit granted therefor under the following conditions and stipulations:

FIRST: If at any time the sources of supply or the water works system or any part thereof shall have become prejudicial to the public health, in the opinion of the Commissioner of Health, then such remedial measures shall be adopted as the Commissioner of Health may approve or advise.

SECOND: On or before the first day of January, nineteen hundred and nine, the Mount Union Water Company shall prepare plans of its entire water works system, showing the area of the watershed and the general topography drawn to scale, the dams and reservoirs, supply mains and profiles thereof, the borough limits and the streets and water pipes therein, with sizes and elevations, gates and hydrants, and file the same in the office of the Commissioner of Health to the satisfaction of said Commissioner, and thereafter at the close of each season's work, a plan of the water pipes laid during the year shall be made and filed in said office, together with any other information in connection therewith that may be required.

THIRD: The water company shall render such assistance to the State Department of Health in making examinations of the water works system and for the supply from time to time as may be required. Should any quarrying operation be undertaken on the watershed, the water company shall immediately notify the Commissioner of Health and adopt such precautionary measures as the Commissioner of Health may prescribe for the sanitary protection of the source of supply of said company.

Harrisburg, Pa., June 30th, 1908.

MOUNTVILLE, LANCASTER COUNTY.

This application was made by the Borough of Mountville, Lancaster County, and is for permission to install a system of water-works for the supply of water to the public in said borough.

Mountville is an old settlement located on the Columbia and Lancaster turnpike, three and a half miles east of Columbia and six and a half miles west of Lancaster, was recently incorporated as a borough and its present population is reported to be about seven hundred and fifty. The citizens derive their chief employment from cigar and tobacco factories, of which there are several. There is also a plow manufacturing company and a brick works.

The village is located on a ridge between the watershed of the west branch of the Little Conestoga Creek which flows southerly and Stricklers Run which flows westerly and discharges into the Susquehanna River at or near the southerly boundary of Columbia borough. It is up the valley of this run that a branch of the Pennsylvania Railroad passes from Columbia to Lancaster. The easterly portion of the borough drains into the Little Conestoga and the westerly portion drains into tributaries of Stricklers Run. The slopes in the borough are sufficient to afford satisfactory surface drainage. The soil is clayey and the underlying rock is limestone. Privy vaults are used in connection with nearly all of the dwellings in the town. There are reported to be very few cesspools.

At the present time the inhabitants derive their drinking water from domestic wells and from cisterns.

There is a demand for fire protection and pressure service and the people desire running water for dwellings. During the latter part of the year nineteen hundred and seven the borough authorities were authorized to incur an indebtedness of twenty-two thousand eight hundred dollars for a municipal water-works plant. A preliminary plan of the source of supply and of the water works system was prepared and publicly discussed before the bond issue was voted upon and it is this project which the petitioners submit for approval.

The proposed source of supply is to be taken from springs located about one mile north of the west end of the borough at a place, or settlement called Chestnut Hill, in West Hempfield township. The springs, three in number, are located in the lower portion of the valley about half a mile long and one-eighth of a mile wide at the head of the main branch of Stricklers Run.

Spring Number One is the most copious one and it is located higher up the valley than the others. In fact, it is, during dry weather the living source of Stricklers Run. Above this spring there is an area of twenty-five acres from which storm water passes in a gully to the run at the spring. Where the water rushes out through the shale rock, a loose stone wall enclosing a space four feet in diameter and backed up with earth two feet in height has been provided as a kind of protection to the spring. The water in this enclosure finds its way out through the stones in the side nearest the run which is two feet distant. It is possible for the surface drainage from the twenty-five acres to backflood into the spring under some conditions. On this area there are four occupied dwellings, three barns in use. The privy vaults on these properties are full to above the surface of the ground and in wet weather the drainage from these vaults and from the kitchens, barnyards and pig-pens goes into the run at the spring. The nearest dwelling to Spring Number One is three hundred feet distant. There is a house, barn, shed and pig-pen here and the privy vault, which is full and overflowing, is located about twenty feet from the dry water course.

The petitioners purpose to deepen Spring Number One, wall it in with tight masonry and cover it over. The water is to be conducted by a three inch cast iron pipe down stream about four hundred feet, where a three inch cast iron pipe from Spring Number Two is to be joined with it into a four inch cast iron pipe, which is to extend down stream a distance of about three hundred feet, across Hill Street, to the proposed collecting reservoir.

Spring Number Two is second in importance with respect to size. It is enclosed in a space four feet square, having brick walls carried to a level with the surface of the ground. The water stands within two feet of the top of the wall. This furnishes living water to the main run which is about thirty feet distant. South of the spring seventy feet distant and sixteen feet higher there is a highway, from which surface drainage at the present time passes onto the side slope leading towards the spring. The nearest residence is on the same side of the highway as the spring. The privy on this property is on rising ground sloping directly towards the spring and not over two hundred and fifty feet away. The vault was overflowing at the time of the Department's inspection.

Spring Number Three is an abandoned well located ten feet west of Hill Street and about one hundred and fifty feet distant from the collecting reservoir proposed. The water level in the well is about twelve feet below the surface of the ground, and above it on a side hill and one hundred and fifty feet away and fourteen feet higher there is a privy with no pit, on occupied property. If it be found necessary and feasible, the flowing water from this well is to be conducted by a three inch cast iron pipe to the four inch pipe above mentioned.

Spring Number Four is located in a barnyard about one hundred and seventy-five feet northeast of the proposed collecting reservoir. It is in the side of a hill, is walled up with loose stone and covered over with plank, the space enclosed being about eight feet long and six feet wide. The walls are two and a half feet high and the water twelve inches deep.

The petitioners purpose to deepen and wall up and enclose and securely protect each spring from surface pollution. Spring number four is to be piped by a three inch cast iron pipe to the collecting basin. The maximum flow, excluding the well, from the springs was measured in October last past to be one hundred and thirteen thousand gallons per twenty-four hours. The minimum flow was measured to be sixty-eight thousand gallons for the same period.

In the forks of the highways, where at present there is a small pond, there is to be erected an open circular reinforced concrete collecting basin, ninety feet in diameter, and eight feet high. In this structure the water from the several springs is to be piped. By means of a receiving chamber and valves the water from any particular spring may be shut off, or it may be delivered directly to the eight inch supply main to town, or it may be delivered to the receiving chamber and thence to the collecting basin. Blow-outs and overflow pipes are provided. The gravity main to the town will draw the water from near the bottom of the reservoir. The overflow pipe will maintain a depth of six and a half feet of water, thus assuring a storage of three hundred thousand gallons.

The top of the wall will be about two feet above the general surface of the surrounding ground. A fence is to be provided about the structure, but no roof will be erected over it.

From the reservoir an eight inch main, thirty-six hundred feet long, will extend to the borough limits. The distributing pipes in the streets of the borough are to range in diameter between four and eight inches. The eight inch pipe is to be thirteen hundred feet long, the six inch pipe three thousand feet long and the four inch pipe fifteen thousand feet long. The highest point of the distributing system is at College Avenue and Main Street, where the ground is eighty-four feet below the level of the water in the reservoir as now planned. This head is equivalent to about thirty-six pounds pressure, with no loss of head due to friction. In the business section of the town the pressure will be about twenty pounds greater.

The original plans, so it is reported, called for a larger reservoir and distributing pipes, the reduction in sizes having been necessary, in order to keep the cost of construction within the amount appropriated by the borough, which said amount represents nearly the full borrowing capacity of Mountville. Bids have been received and the contracts let for the building of the system as now planned. The provision has been made that the plans shall first be approved by the State Department of Health.

There is no reason, known to the Department, why by careful attention to the disposition of sewage on the occupied estates at and in the vicinity of the proposed sources of supply and by careful protection at each spring to keep surface water out, the public health should not be safe-guarded by the proposed plans. The system, however, will not give first class fire service.

It may be necessary in the future to place a roof over the storage reservoir, in order to prevent the abundant growth of certain vegetable organisms, which may thrive in ground water exposed to light.

The capacity of the plant is placed at sixty-five thousand gallons daily and the total estimated consumption should be well within this amount for a number of years.

The plans accompanying the application have not been drawn to scale and they do not show the facilities for drainage of the street pipes.

It has been determined that the proposed source of supply will not be prejudicial to the public health under certain conditions and permission is hereby and herein granted therefor and for the installation of the proposed water works system, under the following conditions and stipulations:

FIRST: That each spring and the well shall be fully protected from surface drainage by means of walls, embankments and ditches and each shall be covered by a roof properly ventilated.

SECOND: The supply pipes from the springs to the collecting reservoir shall be made water-tight and be provided with a valve at each spring to admit of the shutting off of the water.

THIRD: The borough shall make a monthly inspection of every occupied estate on the watersheds of the sources of supply herein approved and shall report any improper disposition of sewage thereon. Receptacles for sewage shall be provided at each such property and be used in a manner to obviate any pollution whatsoever of any waters, which may reach the borough springs by surface or under-ground sources. The borough shall arrange for the prompt reporting to it of the case of any infectious or contagious disease, which may occur at any time on any such occupied estate and said borough shall forthwith file and transmit such notice to the Commissioner of Health and the borough shall file monthly a copy of a report of inspection of sanitary conditions at each such occupied estate, in the office of said Commissioner.

FOURTH: Ample blow-off and drainage facilities shall be provided at low points in the system, accurate plans drawn to scale shall be prepared of each spring and the collecting system and storage reservoir showing all valves and appurtenances, together with accurate plans drawn to scale of the distributing system in the town. Records shall be kept of the operation of the water works on such blank forms as shall be satisfactory to the State Department of Health, and at the close of each season's work a plan of the water pipes laid during the year shall be made and filed with the State Department of Health.

FIFTH: If at any time, in the opinion of the Commissioner of Health, the source of supply or the water works or any part thereof shall become prejudicial to public health, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

Harrisburg, Pa., May 1, 1908.

MUHLENBERG TOWNSHIP, BERKS COUNTY.

(Reading Suburban Water Company)

This application was made by the Reading Suburban Water Company of Muhlenberg Township, Berks County and is for permission to obtain a new source of supply and for permission to furnish water thereform to its consumers in Muhlenberg township.

The community supplied by the Reading Suburban Water Company is primarily a residential suburban district, comprising the village of Hyde Park or Muhlenberg which stretches north from the Reading city line in Muhlenberg township for about a mile and a half along the Kutztown road, extending also for considerable distances on several branch roads. The track of an electric inter-urban car line between Reading and Allentown occupies the Kutztown road throughout the greater part of the village. Hyde Park is at an average distance of two miles east of the Schuylkill river and is located on comparatively flat ground, while east of it the hills rise rapidly.

There are perhaps two thousand inhabitants in this community at the present time. Building operations have progressed rapidly in recent years and bid fair to continue. About one-third of the properties are furnished with water by the Reading Suburban Water Company, while the remainder are said to obtain domestic supplies from individual wells, most of which are dug. There is said to be no public sewerage. Privies are in common use and cesspools also have been constructed, especially for the more modern houses.

The Reading Suburban Water Company was incorporated under the laws of Pennsylvania in one thousand nine hundred and two and first constructed works in one thousand nine hundred and four. It obtains its supply of water at present from the Reading City Water Works in Adams avenue at the city line, through a ten inch pipe supplied through the Reading City distributing system by pumping main from Maiden creek. The ten inch pipe of the Water Company extends north from the city line about one hundred feet and is then reduced to a smaller size pipe. The company's pipes extend north in the Kutztown road about a mile and a half and there are lateral pipes in several of the branch streets, some of them a half mile in length. There is a four inch blow-off in the main in the Kutztown road where the latter crosses Spring Valley creek about one thousand feet north of the city line. It is said this blow-off will drain practically the whole system. About seven thousand feet of pipe are said to have been laid in nineteen hundred and seven, making a total of about nineteen thousand feet of pipe owned by the Reading Suburban Water Company, ranging in size from four to ten inches. Some ten inch pipe has been laid at the northern end of the main at which point it is proposed to introduce the supply from the new source.

There are on the pipe lines about one hundred and twenty-five taps including one for a brewery and one for a dye works. These two factories consume on an average twenty-one thousand gallons per day. The domestic supply is said to average sixteen thousand gallons per day, making a total of thirty-seven thousand gallons. There are no fire plugs connected with the system, though it is said that these could be arranged for should the patrons of the company wish them.

There are no plans of the present system on file in the Department and it is said that complete plans have never been made.

The getting of water from some other source has been made necessary. So it is said, by the action of the city of Reading in refusing to furnish water to the water company after September first, one thousand nine hundred and nine, claiming that such furnishing of water by a third class city is illegal.

The petitioners propose to construct an intake and reservoir on Frush Valley Run at a point about two hundred feet higher than and one and a half miles northeast of Hyde Park and also in Muhlenberg township and to lay pipes and furnish water from said reservoir to their consumers.

Frush Valley Run above the proposed intake has a sandstone drainage area of perhaps two hundred acres on the western slope of the mountain east of the flat ground on which Hyde Park is located. The small run follows a southwesterly course from the upper edge of the watershed to the reservoir site where the company owns about thirteen acres. The distance of the proposed intake below the

summit of the drainage area at the head of the water course is about three thousand feet. Northwest of Frush Valley Run, parallel thereto and at an average distance of two hundred feet, is a public road leading northward into the valley of Laurel Run. The bottom lands along Frush Valley Run are cultivated, while the mountain slopes above are covered with second growth timber.

On the narrow strip of land between the run and the public road are located the dwellings, barns and barn-yards, pig-styes, chicken yards and privies of five farmsteads, having a combined population of about twenty-five persons. For many of these properties the run is the source of water supply for wash water and wash tubs may be seen set up to dry on the banks of the run, so that pollution of the stream seems almost inevitable. Dug wells are the usual source of water supply for other purposes. On the upper side of the road away from the run are five other farmsteads, having also a population of about twenty-five people. The surface run-off from these places collects in the upper road gutter from which a culvert under the road carries the water to the lower side, whence it may reach the run. The township will, it is said, abolish this culvert and provide for carrying the run-off in the upper gutter to below the reservoir site. Inspections made by officers of the Department show that Frush Valley Run may be polluted by privy drainage, barn-yard drainage and by wash water from the properties on the drainage area above the proposed intake. The principal dry weather flow of the run is from springs located at the foot of the steep upper slope of the eastern side of the valley farthest from the habitations.

The Water Company proposes to construct a two hundred thousand gallon concrete or masonry reservoir on flat ground adjacent to the run but well above its flood height and just above this a small intake, whence a six inch pipe provided with a blow-off, will lead to the reservoir. It is desired to use water from this reservoir as soon as possible and as soon as practicable thereafter to replace the intake by a million gallon intake dam, around which the stormy weather flow of the run will be by-passed. When the consumption demands it a nine million gallon impounding dam will be constructed and around this also the wet weather flow will be by-passed. The two hundred thousand gallon reservoir will continue to be used in connection with the impounding dam. The two hundred thousand gallon reservoir will be sixty-six by fifty feet by eight feet deep to the flow line. The masonry walls will be carried one foot above high water level and the basin will be divided transversely by a wall four feet high. The bottom will be of concrete. The six inch inlet pipe will have a connection to each basin, on each of which connections will be a gate valve. Each basin will also have a six inch cast iron drain pipe controlled by a valve to be used for cleansing purposes and to be connected with the ten inch over-flow pipe. An outlet pipe about one and one-half feet above the bottom and protected by a copper screen and controlled by a valve will be installed in each side of the reservoir, the two uniting beyond the valves to form the ten inch supply main. Thus either basin may be cleansed while the water in the other is maintained at a depth of four feet. This supply main will furnish water to the distributing system of the water company at its northern end.

Complete plans have not been submitted of the water-shed, intake, impounding dam, supply main and distributing system, showing the means to be afforded for draining these various parts of the works.

As a future supply, when the consumption shall have outgrown the supply obtainable from Frush Valley Run, the water company has in view large springs flowing from the limestone formation along the banks of Laurel Run at a point about fifteen hundred feet above the mouth of this run in the Schuylkill river. These springs are located about two miles directly west of Hyde Park and when they are resorted to it will be necessary to pump the water taken from them. It would therefore be out of the question to consider the use of this source until the consumption and revenues of the water company have been considerably increased.

Unquestionably from time to time considerable pollution reaches Frush Valley Run above the proposed intake. Even though every precaution be taken, it will be practically impossible to prevent all pollution of this stream during rainy weather. Therefore, the provision of the water company to by-pass the storm flow is a most necessary precaution. Even during dry weather every precaution will be necessary to prevent the pollution of the run. With a daily consumption as reported of forty thousand gallons, the two hundred thousand gallons reservoir will provide for several days settlement, or if necessary will allow of the run-off being by-passed for four or five days. The intake dam when constructed and afterwards when enlarged will provide increased sedimentation. Nevertheless, this would be only a partial safe-guard and in addition all sewage and waste water should be kept out of the stream at all times, to which end it might be advantageous and in the end the cheapest method to construct a collecting sewer up the valley and thereby to convey all the wastes of the inhabitants on the watershed to below the proposed intake and there to purify them in a sewage disposal plant. The Department will cause formal notices to be served upon residents on the watershed from whose properties pollution is reaching the stream and will take subsequent action to the end that the said pollution shall be discontinued and this should make the inhabitants be more willing, for economical reasons, to co-operate with the water company in any scheme for the sewerage of the valley. Only by means of a sewer or cesspools of adequate size and at considerable distance from the run or by providing some other

means for the definite removal of all wastes from the watershed can the run be safeguarded against chance pollution incident to the population residing along the stream. The privy vaults may be reconstructed of water tight cement masonry to be properly cleaned out when necessary, or might be connected to such a sewer system. Even with all these precautions, there will be chance for considerable pollution from barnyards and pig-styes and experience and bacteriological tests of the water furnished from the proposed source may indicate the necessity for other improvements, perhaps for the filteration of the water.

The minimum flow of Frush Valley Run at the site of the proposed intake is thought at times to be less than one hundred thousand gallons per day, perhaps as low as fifty thousand gallons. For this reason it is said to be undesirable to extend collecting pipes to the springs on the eastern hillside away from the habitations and to prevent other water from reaching the reservoir. Such a scheme would incur expensive damages for depriving the people on the water shed of the water of the run in addition to the damages already partially settled for between the water company and riparian owners below the proposed intake.

There is said to be no other available surface supply in the vicinity. Drilled wells have not been considered as a source of supply. It would seem that this idea might be worthy of consideration, especially as it would probably obviate the necessity of paying damages to the owners below the proposed intake. However, the water company officials do not look favorably upon the idea of obtaining a supply from drilled wells and it was represented that the water company would be willing to construct suitable privy vaults wherever necessary on the water shed and to bear some further expense for the improvement of the local conditions.

In view of the method of disposing of sewage in Hyde Park in loose vault privies and cesspools, it would appear to be unfavorable to the interests of public health to necessitate the use of dug wells in the vicinity of these privies and cesspools as the only means of obtaining water for domestic purposes even though the wells are largely used at present, provided a reasonably safe supply can be procured from the proposed source. The condemning of this source might for financial reasons result in the abandoning of the public water works in Hyde Park.

It has been determined that the proposed additional source of supply will not be prejudicial to public health under certain conditions, and a permit is hereby issued therefor under the following conditions and stipulations:

FIRST. Plans for a sewerage system or some other scheme for the definite disposal of the sewage and household wastes of all the properties on the water shed other than into the natural water course shall be filed with and approved by the Commissioner of Health and the works called for in the plans shall have been installed and in operation before the proposed source of supply is used by the Water Company. The Commissioner of Health will use his influence to bring about the co-operation of the inhabitants to a reasonable degree in such a plan.

SECOND. Adequate facilities shall be provided for draining the dam, reservoir, supply main and distributing system of the water works and for by-passing the storm run-off from the water-shed around the intake dam.

THIRD. Detailed plans of the proposed dam, reservoir, supply pipe and of the means of draining these parts of the works shall be filed with the Commissioner of Health and approved by him respectively before these various works are installed, and a detailed plan of the distributing system shall be filed with the Commissioner of Health before water from the proposed source is furnished to the public and thereafter at the close of each season's work plans of the distributing pipes laid during the year shall be filed with the Commissioner of Health.

FOURTH. A plan of the watershed above the proposed intake drawn to scale and showing the location of the water sources, public roads and all buildings and habitations and all other possible sources of pollution shall be filed with and approved by the Commissioner of Health before the water from the proposed source is furnished to the public, and the Water Company shall cause to be made every month, or oftener if necessary, sanitary inspections of the watershed, with a view of discovering any existing pollution of, or menace to, the water supply and reports of such inspections shall be filed with the Commissioner of Health.

FIFTH. Monthly reports of the operation of the water works shall be kept on forms to be suggested by the Commissioner and copies thereof shall be filed with said Commissioner. If the water works or any part thereof, or the water supplied thereby, shall at any time, in the opinion of the Commissioner of Health, have become detrimental to the interests of the public health, then such remedial measures shall be adopted and enforced as the Commissioner of Health shall demand, suggest or approve.

Harrisburg, Pa., August 14th, 1908.

NATRONA VILLAGE, HARRISON TOWNSHIP, ALLEGHENY COUNTY.

Natrona Water Company.

This application was made by the Natrona Water Company of the village of Natrona, Harrison township, Allegheny county, and is for permission to construct a filter plant to be used in filtering water obtained from the Allegheny river and supplied to consumers for general domestic use.

The Natrona Water Company was incorporated under the laws of the Commonwealth of Pennsylvania in April, nineteen hundred and eight, for the purpose of supplying water to the public in the township of Harrison, Allegheny county. The source of supply was stated to be springs situated along the hillsides lying to the north of the Allegheny river and the town of Natrona and near the eastern boundary line of the Pennsylvania Salt Manufacturing Company's farm at Birdvillle and to the north of the Pennsylvania Salt Manufacturing Company's works in Harrison township.

Harrison is a township of the first class, located on the west bank of the Allegheny river in the extreme northeastern corner of Allegheny county and has a population in the neighborhood of fifty-five hundred, of which about forty-five hundred people live in the village of Natrona. This village was established by the Pennsylvania Salt Manufacturing Company when it located its large plant in the township.

The township stretches along the river for a distance of about four and a half miles and back therefrom a little over one mile. To the west is the township of Fawn and to the south the borough of Brackenridge.

Midway of the township there is a ridge elevated about two hundred and fifty feet above the river and extending southerly into Brackenridge borough and northerly into Butler county. Northerly of the village the slopes are precipitous to the river, so that no opportunity affords for extensive building operations; but at the site of Natrona there is a plateau about twenty-five feet above the river and from a third to a half mile wide, extending southerly, so that the area of future growth for the village is naturally confined to the territory beween its present limits and Brackenridge borough.

The hillsides abound in copious springs which form the beginnings of the runs which come down across the flats to the river and these waters afford sources of supply to the public and to the industrial plants for drinking purposes.

The West Penn branch of the Pennsylvania Railroad skirts the foot of the slope. The principal part of the village and the industrial plants are located between the river and the railroad.

There are five important industrial concerns in the township. Their employes reside either in Brackenridge borough or in Natrona. There is about three-quarters of a mile distance between these two places. The land there is either occupied by the industrial plants or is under cultivation.

Of these industrial concerns, the Pennsylvania Salt Manufacturing Company is the most prominent in the village of Natrona. When it located its plant in this locality it laid out streets, water works, drainage pipes, and erected dwellings for its employes. The land developed by said company includes practically everything north of Pond street, which street lies east and west through the central part of Natrona. Here reside fifteen hundred people, whose drinking water is obtained from a spring on the hillside west of the railroad and supplied by gravity. Paralleling this system there is an independent line supplying water from the river for fire protection and domestic purposes. These lines were installed originally by the Pennsylvania Salt Manufacturing Company, but recently the water works company has been organized to control the supply of water to these people under the name of the Natrona Water Company. A similar system of pipes supplies the small settlement of Birdville, located two miles north of the village of Natrona and inhabited by employes of the Pennsylvania Salt Manufacturing Company. This settlement contains about three hundred people.

The village south of Pond street is supplied with drinking water by the Tarentum Water Company of Tarentum borough. The source is the Allegheny river and the water is taken from an intake crib and filtered before being supplied to the consumers.

The other industrial concerns are the Solid Steel Tube and Forge Company, the Inter-State Steel Company, the Allegheny Steel Company and the Reliance Tube Company. These works are located along the river south of the salt company's works. Spring water and drilled well water is used in these works for drinking purposes and river water for industrial purposes.

The existing sewer system of the village of Natrona consists of a combined system of sewers discharging through six outlets into the Allegheny River. These sewers range in size from a sewer four feet square owned by the salt company and used to carry mainly wastes from the plant to twelve inch terra-cotta sewers carrying sewage and storm water from the Walnut street and Pine street district. It is estimated that one-third of the village population permanently and over half that number during the working hours of the day contribute to the pollution of the Allegheny river.

During the early part of nineteen hundred and seven, the township of Harrison made application for permission to extend this sewer system in the village of Natrona and upon reviewing the conditions the Commissioner of Health withheld a permit for these extensions and advised the Commissioners of the township that it would be necessary for them to prepare plans for the collection of the sewage of the village and its conveyance to some point for treatment and purification.

The water works system of the Natrona Water Company, as previously stated, consists of two independent supplies which are used for drinking purposes and for domestic and fire purposes respectively.

The spring water supply is obtained from springs located on the hillside immediately west of Natrona village. The main supply consists of springs located in Potts Hollow, Gagers Hollow and on the slope immediately west of the settled portion of the village. These spring supplies are conducted by gravity to a circular, brick reservoir of one hundred thousand gallons capacity, located on the hill immediately west of the village, and thence the supply is delivered by gravity to the consumers through a system of wrought-iron pipes ranging in size from three inches to one inch.

There are four springs in Potts Hollow which is one-half mile north of the main storage reservoir. These springs are collected by a two inch pipe line and the supply is delivered by gravity into the main reservoir. The other two spring supplies are collected in small reservoirs and thence the supply is delivered to the main reservoir. Each individual spring is walled up and covered to protect it from any contamination.

In Gagers Hollow the reservoir consists of a circular brick tank fourteen feet in diameter and thirteen feet deep with a capacity of thirteen thousand gallons. This tank is covered with a wooden roof.

The tank which collects the water from the group of springs immediately west of the village is similar in design to the Gagers Hollow tank. It is twenty-eight feet in diameter and thirteen feet deep and has a capacity of fifty thousand gallons. From these two tanks the water flows by gravity to the main storage reservoir, which is also a circular tank forty-one feet interior diameter and eleven feet deep. The bottom of this tank is sunk in the ground about six feet in front and the full depth behind. The bottom is composed of an eleven inch concrete floor and the walls are constructed of brick twenty-nine inches thick. Capacity of the tank, as previously stated, is one hundred thousand gallons. From this tank a three inch supply line extends to a two inch main at the outskirts of the village. This two inch main connects with a system of two inch and one inch laterals extending through the streets of the village and connecting with the various houses.

It is estimated that the total flow from these springs is eighty-six thousand gallons per day, of which thirty-two thousand gallons is supplied by the Gagers Hollow springs and fifteen thousand gallons by the Potts Hollow springs. It is proposed to connect eight hundred houses to this supply and it is estimated that the average consumption per house will be fifty gallons per day, so that this would amount to only forty thousand gallons consumption and the supply would be ample. However, great difficulty has been experienced in keeping down the consumption to this amount and already the spring supply is overtaxed.

The Birdville Spring supply is independent from the Natrona supply. The water is procured from springs located on the range of hills along the north side of the Allegheny river east of Birdville. The water is conducted through a two inch wrought-iron pipe system to a collecting tank distant about two thousand feet from the springs and having a capacity of ten thousand gallons. From this tank the water is pumped through a two and a half inch wrought-iron pipe line to a wooden distributing tank mounted on a wooden support and located fifty feet above the ground. This tank has a capacity of ten thousand gallons and from it the water gravitates through the two inch wrought-iron pipe system to the houses in Birdville.

It is estimated that the supply from these springs will average twelve thousand gallons per day. Sixty houses are to be supplied from this system and with an average supply of fifty gallons per house there will be a total consumption of three thousand gallons.

The water works system used for domestic and fire supply consists of a system of pipes ranging in size from six inches to four inches and extends through the streets of the village of Natrona north of Pond street. These pipe lines parallel the spring water supply lines and are supplied with water by the Pennsylvania Salt Manufacturing Company, which obtains water directly from the Allegheny river for industrial purposes.

The six inch main of the Natrona Water Company connects with a ten inch main belonging to the Pennsylvania Salt Manufacturing Company on Center street three hundred feet north of Federal street at the northern boundary line of the built-up section of the village. The water is obtained by the Pennsylvania Salt Manufacturing Company from the river at a point on the northern boundary of the company's works. At this point there are two main pumping stations each located in circular wells twenty-five feet in diameter and thirty feet deep. In the bottom of one of these wells there is a three million gallon Wilson-Snyder pump and in the other well there are two one and a half million gallon Wilson-Snyder compound, duplex pumps. These pumps take the water partly from the river direct and partly through a pipe connected with a crib located about thirty feet from shore in the bottom of the river. Both pump pits are covered with brick superstructures.

For supplying steam for these pumps there is a boiler house equipped with four boilers of six hundred and ten horse power capacity.

The pumps supply water through a ten inch force main to various parts of the works under normal pressure of sixty pounds. For fire purposes there are several large storage reservoirs scattered through the works and these are connected with a fire pump station equipped with Underwriter's Fire pumps of large capacity and capable of giving one hundred pounds fire pressure.

There is also an auxiliary pumping station arranged similar to the two main pumping stations and located in the center of the works. This station is equipped with two one million gallon pumps and is used only in case of emergency. The water for this supply is also taken directly from the river.

It is proposed to close off the direct supply of the water from the Pennsylvania Salt Manufacturing Company's mains at the north end of Center street and to extend the supply pipe from said manufacturing company's mains to a point in the vicinity of the main storage reservoir belonging to the spring supply. At this point it is proposed to install a mechanical filter plant of a gravity type and with a capacity of five hundred thousand gallons per day and to allow the water to gravitate from this filter plant into the existing domestic and fire supply mains in the village of Natrona. A check value will be installed on this supply main immediately outside of the filter plant and during periods of fire the existing connection to the manufacturing company's main at the north end of Center street will be opened and raw water will be admitted to the system for fire protection. This is necessary as the filter plant will be located at an elevation of only one hundred feet above the village and very little storage of clear water is provided.

The filter plant will consist of a settling tank, two gravity filters and a small concrete clear water well.

The settling tank will be located immediately outside of the filter plant and will consist of a circular wooden tank, twenty-four feet in diameter and thirteen feet four inches deep, built of three inch first quality white cedar or Washington fir, and fitted with round iron hoops with draw lugs. It will be located on a concrete foundation extending below frost line. Across the top of this concrete foundation bed there will be laid four by sixes, spaced two feet center to center and on top of those will rest the wooden floor of the settling tank. Above this floor there will be a conical shaped bottom extending on the sides for a distance of three feet above the floor line, to assist in drawing the sludge from the tank. Above the conical bottom there will be three baffles extending vertically across the tank with a four foot opening at alternate ends on each baffle. This will permit of a horizontal circulation of the water and will insure that all water admitted will have the full settling period.

Raw water will be admitted to the settling tank through a weir box located on top of the tank at the end of the baffle furthest away from the filters. This weir box is equipped with a small vertical, distributing weir which is directly connected by means of a small pipe to the alum feed box also located on top of this tank. The full flow of raw water passes this distributing weir and it is arranged so that the proportionate amount of water is admitted through it and into the alum box in accordance with the quantity of solution desired. The water admitted into the alum feed box displaces a proportionate amount of concentrated alum solution and this passes through an effluent pipe located at the opposite end of the feed box at the flow line to a connection in the raw water inlet pipe. The inlet pipe will be controlled by means of a balance valve so as to regulate the inflow in proportion to the consumption of the filters. The water will be taken off from the sedimentation tank at the opposite end from the inlet after it has passed slowly around the three baffles. The sedimentation tank will not be housed, but the alum feed apparatus will be properly protected.

Immediately outside of the settling tank the filter building will be located. It will consist of a substatial brick building covering the two filter units and connecting piping. The filters will consist of two rapid sand filters each eleven feet in diameter and seven feet four inches deep, inside dimensions, built of three inch first quality Washington fir or white cedar and fitted with round iron hoops with draw lugs. Each filter will have a capacity of two hundred and fifty thousand gallons per day when operated at a rate of one hundred and twenty-five million gallons per acre per day. Water will be admitted to the filters through an inlet pipe connection, connecting directly with the outlet pipe from the settling tank and controlled by means of a balance valve equipped with a copper float. The inlet water will flow around two troughs arranged in the top of the filter for washing purposes and thence will be distributed over the surface of the filter. The filtering material will be thirty inches in depth and will be composed of a lower layer of twelve inches of gravel covered with a six inch layer of medium sand, an eight inch layer of fine sand and topped with a four inch layer of a very fine sand. There will be a total water depth in the filter of seven feet, giving a depth of four and one-quarter feet above the surface of the sand.

Water will be drawn off from each filter through a system of strainers arranged in a manifold covering the entire bottom of the filter. The manifold will consist of a steel central section extending across the diameter of the filter from the outlet connection and fed by a system of one and one-half inch galvanized iron pipe spaced six inches center to center and extending crossways on both sides of the filter from the central section. Into these pipes will be screwed special brass strainers patented by W. B. Scaife and Sons, manufacturers of the filters. The whole manifold will be imbedded in concrete which will be carried up to the bottom of the strainers.

The filters will be cleaned by reversing the flow of water in the filter and for the purpose raw water under pressure will be used. The water will be admitted into the manifold through a connection with the raw water main at the outlet end of the filter and this water will pass up through the sand and thence over the wash troughs located eight inches above the surface of the filters. One of these wash troughs extends entirely around the circumference of the filter and there are two cross

troughs extending directly across the filter and connecting with the main trough. These troughs will be formed by bolting a galvanized iron strip to the wooden walls of the filter. The wash water from the filter will be drawn off from these troughs through a connection to the sewer at the inlet end of the filter.

Upon completing the washing operation, a re-wash connection is made with the outlet from the filter so that the water can be wasted after each washing until the filter is running under normal conditions. The outlet from each filter will be controlled by a weir rate controller which will be adjustable and will have a maximum capacity equal to that of the filter.

Immediately under the two filters there will be constructed a clear water well of concrete eight feet wide by eighteen feet long by six feet deep, interior dimensions, and having a capacity of sixty-four hundred gallons. This well will extend under both filters and the filters will be supported above it by means of "I" beams extending across the eight foot width of the wall and carrying four by six struts on which the filter will directly rest. The clear water well will be connected with the supply line to the village.

The Natrona Water Company is chartered to supply spring water to the public in the township of Harrison and has no right, under its existing charter, to furnish an additional supply of filtered river water. Steps should be taken immediately to obtain an extension of its charter rights which will permit it to use this additional supply and the Water Supply Commission should be consulted in regard to this matter.

In using the river supply of water for domestic purposes, which is rendered necessary on account of the limited quantity of spring water, there is a danger of spreading typhoid and other water-borne diseases due to carelessness in the use of this auxiliary supply. The Natrona Water Company appreciates this condition of affairs and on that account has voluntarily submitted the plans for the filter plant to be installed for purifying this supply and eliminating this danger to its employes.

The filter plant as submitted is equipped with all modern appliances, and, if carefully operated, should prove efficient. There are some details in connection with it which have not been provided for in the plans submitted, but which will be neccessary to completely equip the plant. The outlets from the filters are provided with orifice controls which will limit the rate of filtration below the maximum allowable rate, but no provision is made for cutting off the supply from the filter when the small clear water well is full. This can easily be arranged by supplying a control float valve to the outlets. The troughs in the filters are located at an elevation of only eight inches above the top of the sand in the filters. It is the general practice to make the minimum height over the top of the sand to the trough fifteen inches and in many cases where wash water alone is depended upon for agitation and cleaning the filter this distance is increased to a greater depth. The William B. Scaife and Sons Company, who have submitted plans for these filters, claim that this is unnecessary in their filters due to the special arrangement in their nozzles whereby the washing water is forced out horizontally through the gravel and there is a uniform distribution over the whole filter area. However, it appears that it would be more advisable to raise these troughs to a minimum height of fifteen inches above the filter surface.

The plans do not show in what manner the wash water and other waste water from a filter plant will be disposed of. In constructing the plant, special attention should be paid to protecting adjacent property from this waste water. The valve provided between the water company's mains and the pressure lines belonging to the Pennsylvania Salt Manufacturing Company for fire protection should only be opened in extreme emergencies when the fire is sufficiently developed to require this additional supply. The mains, after being filled with raw water from this source, should be thoroughly flushed.

The spring water supply furnished for drinking purposes appears to be satisfactory and the springs appear to be well protected from pollution. It is stated that in typhoid fever epidemics in this locality very few cases have been traced to the water supply from this company.

It has been determined that the proposed source of supply under certain circumstances, will not be prejudicial to the public health, and the plans for the filters are hereby and herein approved and a permit issued therefor under the following conditions and stipulations:

FIRST: That upon the completion of the filter plant the final plans showing the location and piping connections be filed with the Commissioner of Health and that revised plans of the water works showing additions be filed yearly.

SECOND: That the filter plant shall be operated at the rate and under the conditions as set forth in this permit and that modifications in the details of the filter troughs and control valves be made as previously suggested.

THIRD: That accurate records of the operation of the filter plant shall be kept on blanks to be suggested by the Commissioner of Health and reports thereon shall be filed in the State Health Department.

FOURTH: If at any time in the opinion of the State Department of Health the water works system or any part, or the water supplied to the public by the Natrona Water Company is prejudicial to the public health, upon due notice of this fact the water company shall adopt such remedial measures as the Commissioner of Health may advise or approve.

And finally, it is expressly stipulated that permission to do these things is contingent upon the right of the company under its charter to obtain its source of supply from the Allegheny river. If this right is not now a charter right, doubtless the company can secure the privilege by petition to the State Water Supply Commission.

Harrisburg, Pa., December 16th, 1908.

NORTHEAST BOROUGH, ERIE COUNTY.

This application was made by the borough of Northeast, Erie county, and is for the permission to extend its water-works system and to obtain an additional source of supply.

It appears that on February seventh, nineteen hundred and eight, the borough of Northeast, Erie county, made application for approval of plans for a water filter.

It further appears that on June seventh, nineteen hundred and six, the Commissioner of Health issued a permit to the said borough to extend its water-works system and to obtain an additional source of supply. The following were named among the conditions to be fulfilled:

"FIRST: That the borough shall prepare and present detailed plans of the proposed reservoir and dam, overflow, outlet and drainage pipes, gates and appliances and the supply main to the present distributing reservoir, and submit the same to the Commissioner of Health, who may modify or amend them, and the borough shall not begin construction of the reservoir until the plans so approved or amended have been returned by the Commissioner of Health to said borough.

"SECOND: That the filter shall be provided and installed on the line of the supply main between the proposed reservoir and the existing distributing reservoir of the said borough's water-works system according to detail plans to be submitted to and approved by the Commissioner of Health, and no water shall be supplied from the proposed reservoir unless it shall have been adequately purified by said filtration.

"THIRD: That the loam and top soil shall be removed, together with all vegetable matter from the bottom and sides of the proposed reservoir unless in the opinion of the Commissioner of Health such removal shall be deemed unnecessary after further investigation of the subject.

"FOURTH: After the installation of the proposed additional works the borough shall abandon the present pumping station and force mains and also the supply from Baker's creek and thereafter no water shall be delivered from these sources into the present distributing reservoir of the water-works system, either directly or indirectly."

The Department declined to act on the application for the approval of the filter plans until the borough should submit the other information called for in the above quoted permit. In accordance with these conditions the borough on May twenty-third, nineteen hundred and eight, submitted plans for the reservoir and various connections and the supply main.

The present supply of public water comes from a system of springs located in the hills about a mile east of the borough. The flow is piped by gravity to a four-million gallon reservoir, open, located on top of one of the hills southeast and at an elevation of two hundred and thirty-eight feet above the borough. During the dry season this supply is inadequate and it has been necessary to pump from Sixteen Mile creek and to tap Baker creek.

To obviate this pumping and the danger of polluted water from these sources, it was decided to construct a storage reservoir on a branch of Sixteen Mile creek. This reservoir was planned to hold twenty-five million gallons, to have a drainage area of nine-tenths of a square mile and to supply the existing reservoir by gravity through an eight-inch pipe.

This structure has been built as originally planned with respect to location only. It covers an area of sixteen acres and has a capacity of ninety million gallons. The reservoir in shape is approximately trapezoidal. It is formed by an earth dam twenty feet high, constructed across the valley of this creek at a point where it is narrow. The width of the valley at this point is two hundred and thirty feet, the width of the reservoir at the opposite end is eight hundred feet. The length of the reservoir from the dam to the opposite end is twelve hundred feet. The dam extends across the eastern end of the reservoir and is built almost due north and south. It is constructed of earth and is fifteen feet wide at the top with a slope of three to one on the upper side and two to one on the lower side. In constructing this dam a puddle core wall was built across the bottom to a depth of from six to ten feet below the natural surface of the ground into the solid rock underlying this site. This core wall is eighteen feet thick and above the surface of the ground is carried up for a height of four feet in order to tie it into the main body of the dam. A series of ditches were also excavated on the site of this dam parallel to this core wall and were filled with puddle. The main body

of the dam is composed of selected clay, thoroughly rolled and compacted. The slopes are composed of a selected mixture of clay and gravel. The top of the dam is at an elevation of about two feet above the flow line.

On the south side of the reservoir a waste way has been cut into the solid rock. This waste way extends from a point in the creek four hundred feet below the dam, around the south end of the dam, along the entire southern side of the reservoir and thence along the eastern side parallel to the public road. This waste way is ten feet wide at the bottom, thirty feet wide at the top and ranging from four to ten feet in depth. It intercepts all surface flow on these sides of the dam. The spillway for the reservoir is located one hundred and fifty feet east of the south end of the dam and empties into the waste way. It is thirty feet wide and passes over the rock at the point where it enters the waste way. This rock consists of a shale which is liable to disintegrate and it is probable that it will have to be replaced at some time in the future with a concrete lining.

Two twelve-inch cast iron pipe lines are laid under the bottom of the dam surrounded by concrete and connect with a gate house located at the outer toe of the dam. These pipe lines serve as supply and drain lines to the dam. The supply line is connected by a six-inch valve to the six-inch supply main. There is also a twelve-inch bypass on it connecting to the creek and controlled by a twelve-inch valve. The supply is taken from the dam at a point six feet above the bottom through the end of this supply line. The drain pipe connects directly with the bottom of the dam and empties into the creek below the toe of the dam, being controlled by a twelve-inch valve. The inlet ends of both pipes are properly protected by means of screens of one-eighth inch copper mesh. The valve house consists of a re-inforced concrete structure, eight by ten feet, built up sufficiently high above the natural surface of the ground to prevent any wash from the creek and covered with reinforced concrete top.

The reservoir will be supplied by numerous springs located within it and about seventy per cent. of the drainage area through the office of two creeks which cross the waste way in reinforced concrete troughs three feet deep and four feet wide and so arranged that they can be by-passed into the waste way when the quality of water discharged unfits it for use in the reservoir. The drainage from the west of the watershed will be eliminated from the reservoir by means of the waste way so that approximately two-thirds of the drainage area will drain to the reservoir. This will eliminate the drainage from the road, school house and swamp at the east of the reservoir. On the creek which drains in at the southeast end of the reservoir there is a group of houses located very close to the bank which are apt to contaminate the supply. The borough officials have, however, made arrangements with these people to remove all outhouses which are adjacent to the creek and to throw the drainage from this group of buildings into a smaller creek to the north of the buildings, which will drain directly into the waste way.

There is considerably shallow flowage in this reservoir. The depth over the main central part averages twenty feet, but the depth over the bank on the north and south sides ranges from one to four feet for a distance of forty feet from the bank. A part of the bottom and nearly all of the sides were stripped of top soil and other material for a depth of a foot when the reservoir was constructed. There is, however, at present, a great deal of growth in this shallow water and a considerable amount of top soil. At the northeastern end of the reservoir there is swamp from which no material has been stripped and which is very injurious to the quality of water. It is, however, the intention of the borough officials to extend the dyke around the eastern end of the reservoir across this northeastern end and to thoroughly drain the swamp into the waste way. A bank will be constructed between the waste way and the reservoir so as to completly separate the reservoir from the swamp. This has already been done successfully along the eastern edge of the reservoir where a swamp existed before the work was begun.

A six-inch supply main has been constructed from the gate house at this reservoir westerly to the existing reservoir. This main is composed of six-inch cast iron pipes and is seventy-seven hundred feet long. There is a drop of thirteen feet from the outflow pipe in the reservoir for the first thirty-six hundred feet of this main. This gives a controlling gradient of thirty-six ten-thousandths, allowing a flow of two hundred and fifty thousand gallons per day when the level in the reservoir is at the outlet opening of this pipe. The main is supplied with two four-inch blow-off connections controlled by gate valves and located at the two low points on the main between the reservoir and the old reservoir. These blow-offs discharge directly into the nearby creeks.

The proposed filter plant will be located immediately east of the existing reservoir on the force main leading from the impounding reservoir to the distributing reservoir. It will be a pressure type plant. It is proposed to construct immediately one unit of two hundred and thirty thousand gallons capacity, and provision will be made for an additional unit of this size to be constructed in the future. The filter will be located in a reinforced concrete structure sixteen feet long by twenty feet wide by ten feet six inches high, placed below the surface of the ground and entered by an areaway at one end.

The filter unit will be constructed of one-half-inch steel plates, it will be eight inches in diameter and ten feet long.

The drainage system for the filter will be located at a distance of one foot ten inches above the bottom of the cylinder and will be composed of a gridiron of wrought iron pipe varying in size from five inches to one and one-half inches and fifteen inches center to center. The grid will be built in concrete, which will extend from the bottom of the filter to a point immediately above the grid at the face of the strainers. The strainers will be located at the intersection points of the members of the grid and will be of the Hungerford type of strainers. This type of strainer is rectangular in shape and is six inches square by one-half inch deep. It is composed of sheet metal one and one-half inches thick. These strainers take in the effluent from the filter on the four sides and are arranged so as to allow a variation in the openings, due to the difference in pressure. Surrounding the strainers and extending four inches above is a layer of two-inch gravel. On top of this layer there is a four-inch layer of one-half inch gravel and immediately on top of this is a third layer four inches thick of shot gravel varying in size from one-half to one-eighth inch. The sand layer will extend from the top of the gravel and will be four feet deep will be composed of a pure quartz sand of effective size thirty-six and thirty-six hundredths milometer uniformity coefficient of one and two-tenths. It is estimated that the total area of the surface of this filter will be seventy-eight square feet. The inlet pipe of this filter enters through the top of this cylinder and extends longitudinally at a distance of eight inches above the surface. It is composed of a five-inch wrought iron pipe perforated on top with one-inch holes of sufficient number to give an area of ninety per cent. of the area of the five-inch inlet connection. There is a distance of one foot five inches from the center line of this inlet pipe to the top of the filter.

In operating the filter the main from the new dam enters the filter house and is directly connected with an alum chamber for dosing the raw water with alum before it enters the filter. This alum device consists of a cast iron chamber twelve inches in diameter and two feet deep which will hold eighty pounds of alum. It is connected at the top by a three-eighths inch inlet pipe, which also connects with the inlet main extending to the center of same and faces against the velocity direction. The outlet pipe is of the same size connected with the bottom of the alum compartment and with the main at a point below the inlet pipe connection and facing in the direction of the current. By this arrangement a difference in pressure is obtained between the inlet and outlet connections which is directly proportional to the quantity of water being filtered. The quantity of alum admitted to the raw water is further controlled by a needle valve placed on the three-eighths inch inlet connection. After passing the alum connection on the raw water main there will be a device for regulating the loss of head in the filter to a maximum of five pounds. This device will consist of a diaphragm connection with a hydraulic pulley operated valve. The sides of the diaphragm will be directly connected with the raw water and filtered water pipes of this filter. As soon as the loss of head has reached five pounds, the diaphragm will close the hydraulically operated valve and shut off the supply of filter and will remain so until turned on by hand. The outlet pipe from this filter will extend to the existing reservoir and will be controlled by means of an orifice in a steel plate, which will be set to give a maximum discharge of two hundred and thirty thousand gallons under the initial operating pressure on the filter. The flow is further controlled by means of a float valve in the reservoir, which will close off the supply from the filter when the reservoir is full.

In washing the filter the outlet connection with the reservoir will be valved off and wash water will be admitted into the pipe connecting system in the bottom of the filter through a connection with the raw water inlet main. This connection will be made of sufficiently small pipe to limit the initial pressure to twenty-five pounds, which will give approximately eleven gallons per square foot per minute. The wash water is drawn from the filters through the inlet pipe in the top, which has a five-inch connection with the vitrified sewer line leading to Sixteen Mile Creek. After washing the filter the outlet pipe is further connected by means of a three-inch pipe with the sewer drain, so as to allow the water which is first filtered to be wasted.

The filter will rest on a concrete foundation, will be equipped with a manhole in front above the sand line and will have pressure gauges on the raw water and filtered water connections to show directly the loss of head in the filter at any time.

The piping connections at the filter are so arranged that the line from the new dam passes directly into the filter plant through the filter and along the north side of the old reservoir to the existing supply main from the springs. There is also a six-inch by-pass around the filter which will permit the water from the new dam to be directly passed into the existing supply. A ten-inch sewer drains from the bottom of the filter plant southerly to Sixteen Mile creek located three hundred and fifty feet distant.

The Baker creek line is also supplied by two springs located above Baker creek near the end of this line. These springs are connected by a four-inch wrought iron pipe connected under Baker creek to a manhole located on the opposite side. There is also a connection in this manhole to Baker creek. The two springs are above the flow line of the creek and there is no contamination in the direct vicinity which would affect the purity of the water from these springs.

In constructing the reservoir and supply line before the plans for same had been submitted, the borough violated the conditions of the permit and the State law.

The reservoir as constructed has a capacity of three times that contemplated in the original plan. Whether this was good judgment or not remains to be demonstrated, but one thing is sure that the large percentage of shallow flowage is a menace to the quality of the water.

On July seventeenth, nineteen hundred and eight, there was absolutely no flow into this reservoir from the surface streams and there was no overflow from the spillway and no water was being drawn out through the pipes. In the absence of any evidence of leakage, it appears that in drouths the yield of the watershed for short periods is nothing. However, the average flow from the drainage area during the wet months and for the year should be ample to fill the reservoir annually. The storage thus available is intended to be used and drawn upon only during the dry season. The problem is to keep this stored water in a good and satisfactory condition for domestic purposes.

As there is considerable shallow flowage, special attention should be paid to stripping all shallow areas. This should be completed around the entire edge. The swamp at the upper end shoud be eliminated before the supply is used. A dyke or earthen embankment should be built to effectually isolate the swamp water from the reservoir. The water in the reservoir at the present time is much discolored, due, in a great measure, to the swamp and other shallow flowage.

A six-inch suppiy main has been constructed from this reservoir to the old reservoir in place of the eight-inch as originally planned. As stated above, the supply from this main is limited to two hundred and fifty thousand gallons per day, and if a greater quantity than this be needed in the future it will be necessary to lay another six-inch supply line. As this supply is merely an auxiliary to the spring supply, and as the growth of the borough has been very slow in the past, it is probable that the six-inch line will furnish an auxilliary supply to the borough for many years to come.

In a filter plant of the pressure type there is always a disadvantage due to the difficulty experienced in inspecting the surface of the filter. It is necessary to remove a manhole located in the end of the filter and above the sand line, and after removing it to illuminate the inside of the filter and sometimes crawl in. There is a tendency for the operator to neglect to do this after every cleaning. With the automatic devices proposed for controlling the filter, there should be no trouble in furnishing the correct proportions of alum and in properly controlling the rate and loss of head. Hungerford and Terry, the contractors for the filter, have promised to guarantee its successful operation for one year after the date of installation and will make bacteriological and chemical analyses at sufficient intervals to intelligently operate the plant.

The by-pass from the new supply around the filter plant should be eliminated. This will remove any temptation for the operator to supply the town with raw water from the new reservoir.

It has been determined that the proposed auxiliary water supply will not be prejudicial to public health, and a permit is herein and hereby granted therefor and for the proposed filteration plant as hereinbefore described under the following conditions and stipulations:

FIRST: That before using the supply the borough complete the waste way around the dam so as to completely drain the swamp at the northeastern end of the dam. The parts of the reservoir where there is a shallow flowage of six feet or less in depth are to be stripped thoroughly of all loam and top soil.

SECOND: That weekly sanitary inspections of the condition of the watershed above the new reservoir shall be made by the borough, and all things be done by the borough to eliminate contamination by sewage of the waters from the watershed to be used as a source of supply to the public in the borough, and copies of such sanitary weekly inspections shall be filed in the office of the Commissioner of Health.

THIRD: That the filter plant shall be operated at the rate and under the conditions described in this permit. The by-pass around the filter is to be eliminated and the inspection manhole is to be removed after every washing when the filter is in operation.

FOURTH: That in abandoning the Baker creek supply the borough is permitted to use the two springs connected to their line at present and located immediately above Baker creek at the end of this line. Especial care is to be taken in sealing off the connection with Baker creek and in arranging the manholes at this end so as to allow no seepage from Baker creek.

FIFTH: That if at any time the Commissioner of Health determines that said supply is unsuitable for drinking purposes, the borough shall adopt such precautions and apply such remedies as the Commissioner of Health may prescribe.

SIXTH: Accurate records of the operation of the filter plant shall be kept on blanks to be suggested by the Commissioner of Health and reports thereof shall be filed in the State Health Department.

SEVENTH: At the close of each season's work accurate plans of the water pipes laid during the year in the streets of the borough shall be made and filed in the office of the Commissioner of Health, together with any other information in

connection with the water works system that may be required, to the end that the Commissioner of Health shall always be informed of the extent of the water works system and the use thereof.

Harrisburg, Pa., August 10, 1908.

ORBISONIA, HUNTINGDON COUNTY.

(Orbisonia Water Company).

This application was made by the Orbisonia Water Company, of Orbisonia, Huntingdon county, and is for permission to install a system of water works for the supply of water to the public in said borough and the adjoining borough of Rockhill.

The Orbisonia Water Company is not an organization incorporated under the laws of this State. It is an association of three men, citizens of the borough of Orbisonio, namely, S. O. Fraker, C. B. Bush and W. K. Shaffner. Since the filing of the above application these gentlemen have requested further permission to supply the adjacent borough of Rockhill.

It appears that on October first, nineteen hundred and seven, the Orbisonia council passed an ordinance authorizing the proper officers of said borough to enter into a contract with the said Fraker, Bush and Shaffner and other persons who may be hereinafter incorporated or associated with them in the water company to be known as the "Orbisonia Water Company," for the erection, construction and maintenance in the borough of a complete water works system for the furnishing at all seasons of the year of a sufficient quantity of pure water for domestic, sanitary and manufacturing purposes, and for the further supply of water to provide protection against fire to buildings and property within said borough, at such time and upon such terms as may be agreed upon in the future.

It also appears that on January first, nineteen hundred and eight, the council of the borough of Rockhill granted a similar franchise to the said Fracker, Bush and Shaffner, styled the "Orbisonia Water Company." In both appears the stipulation, "that the franchise, property, stocks, bonds and capital of the said Orbisonia Water Company shall be exempt from all borough taxation." So far as the Department is informed no attempt to issue bonds or stocks has been made. The obligations assumed by the gentlemen above named are individual obligations.

The boroughs of Orbisonia and Rockhill constitute a single community of about fourteen hundred inhabitants dependent principally upon an iron ore furnace in Rockhill and also to a considerable extent on farming and coal mining in the vicinity. The boroughs are located on opposite banks of Black Log creek, one mile above its junction with the Great Aughwick creek, which eleven miles below and north of Rockhill joins the Juniata river four miles below Mount Union. The boroughs are entirely within Cromwell township in the southeastern part of Huntingdon county. The East Broadtop Railroad, a narrow gauge line runs from Mount Union through Shirley borough to Rockhill and Orbisonia, and thence westerly twelve miles to two bituminous coal mines at Robertsdale, a five-mile branch extending southeast from Orbisonia to Shade Gap. About thirteen hundred tons of coal are hauled daily from Robertsdale.

The valley of the great Aughwick, extending in a general direction east of north, is here from three to five miles wide, and is bounded on the east by a belt of high mountain ridges about fifteen miles wide, beyond which is the Cumberland Valley, and on the west by Jacks mountain, and beyond it by Broadtop mountain, in which are the coal mines. Fertile farms cover the bottom land of the valley and of the valleys in the mountains to the east.

The furnace in Rockhill is owned by the same people as the railroad company, but is leased to and is operated by the Rockhill Furnace Company. It was shut down, occasioning hard times in the community, about ten years ago, and has again been shut down since the investigation by the Department, so it is reported. All the coal is obtained from Robertsdale, being but a small part of the product of these mines, and is coked in Rockhill. The ore is principally lake ore, although a small proportion is mined locally in the mountains in the east.

A small pin factory is located in Rockhill, and in Orbisonia there are a grist mill and small planing mill.

Orbisonia marks the site of some of the oldest charcoal iron furnaces in the country. The village became a borough in about eighteen hundred and fifty. The town of Rockhill was laid out in eighteen hundred and seventy-four and became a borough in about eighteen hundred and eighty-six. The growth has been irregular. At present the population is less than it was in eighteen hundred and ninety; for Orbisonia borough and for Rockhill borough it is about stationary.

The assessed real estate valuation for Orbisonia is said to be about one hundred thousand dollars and the debt about two hundred dollars, all for school purposes. There are no paved streets, other than macadam, public water works, nor is there public lighting. Two short combined sewers run from Ridgley Street to Black Log creek, one in Elliott Street and one between Elliott and Ashman

Streets. The assessed valuation of Rockhill is about one hundred thousand dollars. There are no paved streets, public water works nor is there sewerage or public lighting.

The present water supply for domestic purposes is obtained almost exclusively from dug wells and rain water cisterns, both in Rockhill and Orbisonia. The residential districts in both boroughs are comparatively closely built up. There is a loose-lined privy vault for practically every house, although there are few if any cesspools. Limestone, sandstone and shale underlie the town, the former outcropping in Orbisonia. The formation and the close proximity of privies and dug wells render extremely dangerous the present domestic water supply. Moreover, the supply obtained from the wells is too hard for domestic purposes, as indicated by the storage of rain water which is, however, palatable.

A pumping station, reservoir and auxiliary fire pumps are maintained by the furnace company for its own use, the source of supply being Black Log creek, at a point near the furnace.

The local authorities do not report their contagious diseases to this Department. Dr. Taylor, President of the Council of Orbisonia, reported having had three cases of typhoid in Orbisonia this fall, from foreign infection, he thought. Several years ago he had twenty-seven cases in the vicinity, but does not consider the local wells suspicious or dangerous.

Dr. C. B. Bush, one of the principal local physicians, a member of the Council of Orbisinia, and one of the petitioners in the application under consideration, reported having attended within the past twenty years fifty-four cases of typhoid in Orbisonia and sixty-six in Rockhill, a fair proportion having been serious, several resulting in death. He blames the local wells, giving as one reason the usual persistency of the disease on any property once visited.

Owing to the seemingly dangerous conditions of the wells and to the desires of several of the inhabitants for modern sanitary improvements the question of the borough introducing a water supply was recently brought to public notice and voted down in June, nineteen hundred and seven. The people remembered vividly the hard times following the shutting down of the furnace a decade ago and, in view of the possibility of the recurrence of these conditions, feared to incur an increase in taxation. The introduction of a purely private supply by those persons wishing it was considered, but this idea was dropped and finally the ordinance already sited was passed by the Council of Orbisonia.

The water works design, approval of which has been applied for in the formal application under consideration, and altered as set forth in letters to the Department subsequent to the application, contemplates an intake to collect the flow of a mountain spring incidentally developed in an iron ore drift, a gravity pipe line thence to a storage or equalizing reservoir and thence a gravity pipe line to Orbisonia and distributing pipes in Orbisonia and Rockhill boroughs.

Black Log creek has its principal sources in the second valley east of the Great Aughwick creek, draining the valley both to the north and to the south, and then turning to the west at right angles it flows through gaps in the intervening ridges and joins the great Aughwick. Rockhill borough is in the fork of the creeks, the town being on the banks of Black Log creek one mile above the fork, while Orbisonia is on the opposite bank east of Rockhill. There intervenes between the two towns on the western or Rockhill side of the creek a flat about one thousand feet wide and occasionally inundated. The furnace is located on this flat and the railroad traverses it at the foot of the rising ground on which slope is located Rockhill. The Orbisonia bank rises abruptly and the town is close to the stream at an average elevation of twenty feet or more above it.

Sandy run rises in the valley west of that in which Black Log rises and flows south and then west just north of Orbisonia, entering Black Log below that town. A public road from Orbisonia extends up the valley of Sandy run.

The proposed source of supply is a spring in "Old Williams Drift," located about a mile and a half northeast of Orbisonia in the western slope of Black Log mountain, which drains to Sandy run. The drift was opened several yeare ago as an iron ore mine and abandoned owing to the difficulty of handling the water. It is said to extend two thousand feet or more into the hillside and to slope sufficiently to drain it. It is at an elevation of about nine hundred and fifty feet above tide and three hundred feet above the average elevation of Orbisonia. The drift is about one-third way from the bottom of the valley to the mountain top. The general dip of the strata in Black Log mountain is about seventy degrees to the west. It is said that there is an "S" shaped fold in the strata in the mountain in this locality, east stratum below the fold being west of its continuation above, making a narrow bench in the side slope on which numerous springs crop out at or above the elevation of the old drift. The drift and several of these springs which are considered possible additional sources are on the property of the Rockhill Iron and Coal Company, more or less intimately connected with the railroad and furnace companies, and it is said that the right to the water has been acquired under condition that a supply be furnished to the office of the furnace company.

Besides the ore vein and several strata of shale and slate, the drift extends through one of limestone which, however, is said not to make the water hard. The flow from the mine is said to vary but slightly, to be little affected or not at all by rainfall, and to have measured in August, nineteen hundred and seven, a little more than two gallons in five seconds, or about thirty-five thousand gallons per day.

The mountain side above the drift is wooded and apparently uninhabited, which is said to be the case and as well on the eastern slope at a greater elevation than that of the drift.

Plans of the intake and of the possible tributary drainage area have not been submitted.

A three-inch pipe is to lead southwesterly from the drift five thousand six hundred and thirty-eight feet to a proposed reservoir at an elevation of about one hundred and eighty-five feet below the drift, said pipe line to extend entirely through private property. A plan and profile of the location of the pipe line have been submitted, and although facilities for draining it are not indicated on said plans, a letter subsequent to the application states, "The low points on line from drift to reservoir will have flush outs."

Plans of the proposed reservoir have not been submitted, nor any information as to its size, character, material of construction, whether it is to be covered or open, or the facilities for draining it.

From the reservoir site a four-inch pipe is to lead to Orbisonia, the length of pipe from the reservoir to the borough line being about two thousand four hundred feet. The line will run in a general southwesterly direction eight hundred and sixty-eight feet in private property and about fifteen hundred feet in the public road in the valley of Sandy run. A plan and profile of the location of the pipe line have been submitted, and although facilities for draining it are not indicated on said plans, a letter subsequent to the application states that there will be flush outs at the low points on line from reservoir to borough line.

The distributing system is to consist of about sixteen hundred feet of four-inch mains and about thirty-five hundred feet of smaller pipes in Orbisonia and fifteen hundred feet of four-inch pipe in Rockhill, extending across the flat to the town and the office of the furnace company.

The elevation of the reservoir above the area to be served averages about one hundred and twenty-five feet for Orbisonia and one hundred and forty-five feet from Rockhill, although the part of Rockhill on the hillside extends to perhaps fifty feet above the locality to be served at present.

There is to be a valve on the supply main where it enters Orbisonia and a valve in Orbisonia on the main leading to Rockhill. There are also to be valves on the smaller distributing pipes where they lead from the four-inch mains. There will be six or more dead ends in the system. The pipe may be carried across the Black Log creek, either in the bed of the stream or on the public highway bridge connecting the towns. There is to be a blow off in Rockhill at the bank of the creek. The approximate locations of this blow off and of four or five fire plugs to be installed in Orbisonia and also of the distributing pipes were indicated by one of the applicants at the time of the Department's inspection. It was not then definitely known what might be the most desirable location of the pipes of the distributing system.

Not a great number of consumers are expected in the near future in Orbisonia and but very few in Rockhill. It will be noted that the ordinance of neither borough requires that the system now to be installed shall provide fire protection.

With the elevations as given of the mine drift and reservoir a three-inch wrought or cast iron pipe would be more than ample to carry the entire flow of the spring in the drift, reported to be thirty-five thousand gallons daily.

The intake arrangements should provide reasonable protection against chance or malicious pollution and facilities for being drained.

The size of the reservoir required depends upon whether storage is to be provided against a protracted drought and incidental fires or whether the storage is to provide for a fire supply and the inequality in the rate of consumption during the day or merely the latter inequality without attempting to provide fire service. The design of the reservoir should anticipate the possible necessity of its having to be covered to obviate trouble from algae growths and ample facilities should be provided for draining said reservoir and for shutting it off from the pipe below so that the latter may be drained.

With the elevations given for the reservoir and Orbisonia and Rockhill the four-inch main from the reservoir to and in the boroughs would not have the capacity to provide a single standard fire stream, such as required by fire underwriters. A six-inch pipe would be better, but it would require an eight-inch pipe to insure two or more fire streams after the pipes have been but a short time in use. The four-inch pipes proposed would be ample to carry the entire flow of the spring and an additional flow such as might be conducted to the reservoir from some of the other springs already mentioned as being in the neighborhood of the drift.

The distributing system would with advantage be altered in design so as to provide facilities for its more complete draining and so as to eliminate dead ends as far as possible.

Even if the ordinary demands to be made of the system are solely those of domestic consumption the supply may prove insufficient during protracted droughts unless considerable storage is provided; but since such a failure would not necessarily imperil the public health the possibility of its occurrence need not necessitate the withholding of approval of the system.

The borough authorities and all persons interested should know that the State Health Department approves the proposed design simply as one for system to obtain a safe domestic water supply and not to provide fire service, and further that the future use of any part of this system to supply for purposes water which from a

sanitary or public health standpoint may be less satisfactory than the supply proposed at the present may appear to be prejudicial to the interests of public health.

It has been determined that the proposed source of supply and the proposed system of water works will not be prejudicial to public health under certain conditions, and a permit is hereby issued therefore under the following conditions and stipulations:

FIRST: That a plan of the tributary watershed above the proposed intake be prepared by the applicants, named the Orbisonia Water Company, on which plan shall be plotted the lines of all lands purchased or leased or in which the said water company may have an easement, and all highways and occupied estates, should there be any, and such plan shall be filed with the Commissioner of Health on or before the completion of the construction of the proposed intake.

SECOND: The said water company shall cause to be made every three months a sanitary inspection of the tributary watershed above the intake, and reports thereof shall be made to the Commissioner of Health.

THIRD: All natural ground surface to be flooded by the proposed intake or to be made part of the sides or bottom of the proposed reservoir shall be thoroughly grubbed and cleaned, and all organic matter and mud shall be removed therefrom.

FOURTH: Ample facilities shall be provided for the proper and complete draining of any basin formed at the intake and of the reservoir and for the protection of the intake and of the reservoir from chance or malicious pollution and also for the shutting off of the supply from the town if need be. Detailed plans of the intake and reservoir and of these facilities for drainage, and all pipe connections and valves shall be submitted to the Commissioner of Health for approval before the works are constructed, and no additional source shall be used or new reservoir constructed thereafter unless approved by the Commissioner of Health.

FIFTH: Ample facilities for ready draining of the upper and lower supply mains at low points shall be provided. A plan of the boroughs showing the streets and showing definitely the location and sizes of the proposed water pipes and blow-offs and the location of all gates, hydrants and the drainage facilities shall be prepared and filed with the Commissioner of Health. At the close of each season's work a plan of the extensions to the street mains laid during the season shall be prepared and filed with the Commissioner of Health.

SIXTH: Because the small sizes of proposed pipes might involve public health, it is expressly stipulated that approval of them is herein given on the condition that the borough councils shall also approve the sizes after having been acquainted with the discussion of the subject already presented; reserving the right, however, to immediately modify this stipulation if it should appear to be for the interest of public health to do so.

SEVENTH: If at any time in the opinion of the Commissioner of Health the said source of supply or the water works or any part thereof have become prejudicial to public health, then such remedial measures shall be adopted as said Commissioner may advise or approve, and such reports of the monthly operation of the system shall be made to the Department of Health as may be required.

It is the intention of the State Department of Health to occasionally collect samples of water from the proposed supply and to make tests thereof, and in accepting this permit the water company obligates itself to co-operate with the State officials.

It is expressly stipulated that this permit is issued under the further condition and provision that the water company shall have complied with all laws applicable to the case relative to the business in which it proposes to engage.

Harrisburg, Pa., April 2, 1909.

PARKESBURG, CHESTER COUNTY.

Parkesburg Water Company.

This application was made by the Parkesburg Water Company, of Parkesburg borough, Chester county, and is for permission to obtain an additional source of supply of water to the public within its charter territory.

It appears that the borough of Parkesburg is located in the northwestern part of Chester county, on the main line of the Pennsylvania Railroad. It has an area of about five hundred and seventy acres and a present population of about two thousand; in nineteen hundred it was seventeen hundred and eighty-eight, and in eighteen hundred and ninety, fifteen hundred and fourteen.

The borough is drained by the west branch of Buck run, which empties into the Brandywine about five miles below Coatesville. This stream receives surface drainage and sewage from borough sewers built in the two principal streets of the town, to which many houses are connected. There are also several private sewers emptying into this stream.

There are from twenty-five to fifty individual wells in use in the borough.

The soil is clay and gravel underlaid by sandstone. The principal industry in the town is the Parkesburg Iron Company. Judging by present conditions there would appear to be no indications of a rapid growth of the borough in the immediate future.

The Parkesburg Water Company was incorporated in eighteen hundred and ninety-nine, to supply water to the public in the borough of Parkesburg. An ordinance of borough council, passed in eighteen hundred and ninety gave the borough the right to lay pipes in the streets and contracts for fire service were entered into. The works were built in that year and have been extended from time to time as necessity demanded. At present the territory furnished with water comprises about one hundred and forty acres. The works are reported to have a capacity of seventy-thousand gallons daily. The supply is taken from driven wells, eleven of which are located at the lower reservoir just north of Main Street, and two at the upper reservoir, about twelve hundred feet further north.

Main Streets parallels the railroad tracks and lies immediately north of them.

The wells at the lower reservoir are six inches and eight inches in diameter and from thirty-six to one hundred and fifty feet deep. These wells empty into a settling reservoir near Main Street, thirty-two feet by seventy-six feet by six feet deep to overflow, having a capacity of about one hundred and ten thousand gallons.

From this reservoir water is pumped by a gasoline and oil engine pumping plant through about three hundred feet of six-inch pipe to the eight-inch main connecting the upper reservoir with the distribution system, which is about thirteen hundred feet in length. The wells at the lower reservoir are located at the foot of the valley, in which there are about thirty houses, all of which are reported to be provided with privies. The wells and lower reservoir are protected from surface drainage, but there is a possibility of pollution from some of the above mentioned houses.

The upper reservoir is one hundred and fifty feet long and one hundred feet wide and eleven feet deep to the overflow line, with vertical masonry walls. It is divided into two parts, one one hundred feet by fifty, and the other one hundred feet by one hundred, but they are operated as one reservoir. They have a capacity of about one million, two hundred and thirty-eight thousand gallons. They are provided with blow-off and overflow pipes, and receive the surplus from the pumps.

At this reservoir are located two wells about three hundred feet deep, the water level of which stands about ninety feet below the surface and can be utilized only by pumping. All of the wells are driven into mica sandstone, the top of which lies about twenty feet below the surface.

The distribution system consists of eight hundred and fifty feet of eight-inch, forty-five hundred and fifty feet of six-inch, eleven thousand eight hundred feet of four-inch, and two thousand feet of two-inch, or a total of twenty thousand four hundred feet, or about four miles.

The estimated supply of ground water is about sixty-five thousand gallons per day minimum and seventy-five thousand gallons per day maximum. The total consumption is given at seventy-five thousand gallons daily, which is the full amount of the supply, or about fifty gallons per capita based on fifteen hundred consumers.

The proposed supply is located at the headwaters of Glen run in Highland township, about two miles southwest of the town.

The supply consists of sixteen springs located in a piece of swampy ground covering about six acres. These springs have been excavated from two or three feet to sandstone rock, walled up and covered with flat stones.

They have been connected with a receiving reservoir by means of three-inch, five-inch, six-inch and eight-inch terra cotta pipe, laid with loose joints in trenches excavated to rock. There are about four hundred and forty feet of three-inch, four hundred and forty feet of five-inch, three hundred and eighty feet of six-inch and one hundred and seventy feet of eight-inch pipe in these ditches besides about two hundred and fifty feet of French drain, making a total of one thousand six hundred and eighty feet of loosely laid pipe with open joints which collect more or less ground water.

The total yield has been estimated at three hundred thousand gallons per day.

The flow from these pipe lines is collected in a concrete reservoir nine feet by five feet by four feet deep, having a capacity of thirteen hundred and fifty gallons. This reservoir will be covered with a wooden roof.

From this reservoir an eight-inch cast-iron main is laid for about one hundred and forty-four feet, from which about two and a half miles of six-inch pipe conducts the water to the lower reservoir near main street.

The swamp in which the springs are located is situated near the head of Glen run, there being about one hundred and twenty-five acres of farming country above the swamp.

Within about two hundred feet of the French drain, at the head of the swamp, is a tobacco shed. A water course spreads its flow over this swamp and on this water course is located the large farm buildings of W. A. Griest.

On this farm are kept about ten or twelve horses, thirty or forty cattle and fifty hogs. The hog-pen is about five hundred and fifty feet long and the water course traverses about two-thirds of its length and also receives drainage from barnyard, kitchen and from privy vaults, the contents of which are above the

ground. The farm buildings are probably five hundred feet above the swamp. There is also another property owned by the same party where a few pigs are kept, but no stock, about one thousand feet above the swamp, the drainage from which follows the road to the swamp.

The supply will be ground water in dry weather and during storms it will be polluted surface water, filtered through from two to three feet of clay and gravel.

Evidently an additional source is needed. The improvements had been practically completed at the time of the Department's inspection. Aside from the pollution mentioned, it is evidently a good supply.

The course of the stream discharging into the swamp can be led around it, thus greatly decreasing the danger of pollution.

There has been no satisfactory plan of the proposed supply filed with the Department and no reference is made to any possible pollution in the application; in fact, the application states that it will be free from pollution.

It has been determined that the water works and the proposed source of supply is not prejudicial to public health and a permit is hereby and herein granted for the additional supply and for extension of water pipes in the borough, under the following conditions and stipulations:

FIRST: That the water company shall prepare a map of each watershed, showing its limits and all streets and ways, occupations and sources of pollution thereon, and file the same with a satisfactory report thereof in the office of the Commissioner of Health within ninety days from the date of this permit, and thereafter the water company shall co-operate with the Commissioner of Health in enforcing all such regulations with respect to the disposal of sewage on said watershed as may be deemed advisable.

The attention of the water company is called to the fact that the law prohibits the disposal of any sewage from private estates into any waters either on the surface of the ground or under the surface of the ground.

The information herein called for is to be a basis for the determination of whether there be any such sewage discharged in any way on the watershed to the menace of the source of supply of the water company and to the public health within the water district of said company.

SECOND: Within ninety days from the date of this permit the water company shall prepare and file maps showing the location of the various springs and a plan for diverting the flow of water courses from the vicinity of springs, and when such plan shall have been modified, amended or approved by the Commissioner of Health, the water company shall execute the same forthwith in order that the source of supply may be safeguarded against possible pollution.

And on or before said ninety days shall have expired, the water company shall also have filed in the office of the Commissioner of Health a plan of the pumping station, piping and wells of existing supply and of the reservoirs and of the distributing pipes from the source of supply and the pipes in the streets, showing their size, elevations, location of gates, hydrants, blow-offs and drainage facilities. If, in the opinion of the Commissioner of Health, such drainage facilities are inadequate, then improvements shall forthwith be made to the satisfaction of said Commissioner.

THIRD: If at any time, in the opinion of the Commissioner of Health, the water works or any part thereof, or the source of supply shall have become prejudicial to the public health, then such remedial measures shall be adopted by the water company as the Commissioner of Health may advise or approve. The water company shall keep a record on blank forms satisfactory to the Commissioner of Health of the operation of its system and file copies thereof with the said Commissioner. Examinations and investigations of the system will be made from time to to time by the State Department of Health and the water company shall assist if required to do so in such examinations and investigations.

The State Department of Health may make rules and regulations for the operation of the system in so far as the interests of the public health are concerned and such requirements shall be observed by the water company.

Harrisburg, Pa., July 21, 1908.

PITTSBURG, ALLEGHENY.

Approval is hereby given of plans for the construction of ten additional water filters at the city's filtration works near Aspinwall, and general approval to the entire water works system for the enlarged city of Pittsburg, and a permit issued for such additional water filters and for general extensions to the water works system in response to plans duly filed by said city of Pittsburg and a written statement supplementary thereto.

GENERAL CONDITIONS.

The territory comprising the greater Pittsburg district as incorporated in one municipality, now includes "Old Pittsburg" or all the land laying east of the confluence of the Allegheny and Monogahela rivers between the former on the north and the latter on the south, for a distance of about seven miles in which reside approximately three hundred thousand people; also the "South Side" or the land

along the south bank of the Monongahela river opposite Pittsburg proper, a stretch of four miles and westerly along the south bank of the Ohio river for two and a half miles in which reside approximately one hundred thousand people; and also the "North Side" or all the land on the north bank of the Allegheny opposite old Pittsburg, a stretch of about three miles and westerly along the north branch of the Ohio for about three miles, formerly the city of Allegheny, in which reside approximately one hundred and fifty thousand people.

Beyond the site as described, there are in the immediate vicinity many municipalites which are closely allied with Pittsburg. Numerous territorial accessions by annexation have been made to Pittsburg in the past. It was under the provisions of Act number one hundred and sixty-one, approved April twentieth, nineteen hundred and five, providing "that where two cities are contiguous and in the same county, the smaller may be annexed to the larger,," that Allegheny City was absorbed.

The annexation idea is predominant and this tendency is of more than passing import.

Ranking fifth among the cities of the United States in commercial and industrial importance—because it is the port of entry and transfer between the east and west and because it is the largest shipping point for bituminous coal and because it has the natural fuel supply of coal, coke and gas and the climate to foster enterprise—no period of its expansion has been more promising than the present. Local problems pertaining to public water supply may with peculiar reason be contemplated in relation to probable consolidation.

The past conditions of growth offer a partial explanation of the different independent water works systems found existing within the municipal territory of Pittsburg to-day.

In old Pittsburg, comprising Wards one to twenty-three, inclusive, Brushton borough, now Thirty-seventh ward and Sterrett township, now Forty-first ward, there are two systems, one owned by the municipality and the other owned by a private corporation, named the Pennsylvania Water Company, authorized to supply water to the public in said borough and township prior to their annexation to the city.

In the "South Side" the water is furnished by two private corporations; one being the Monongahela Water Company, supplying wards twenty-three to thirty-six, inclusive, and the Thirty-ninth and Fortieth wards—formerly Elliott and Esplen boroughs—and the other being the South Pittsburg Water Company, supplying Wards Thirty-eight, Forty-two, Forty-three and Forty-four, formerly Beltzhoover, Montooth, Sheraden and West Liberty boroughs, respectively.

The old city of Allegheny, now the "North Side," has its own system.

OLD PITTSBURG WATER SUPPLY.

Taking up each system in the order stated, with respect to the old Pittsburg water supply, it is noted that the topography in the city proper is so uneven, elevations ranging over five hundred feet, that distinct systems of distribution have resulted. However, all water is primarily lifted into the Highland Park reservoir from the Brilliant Pumping Station. This plant is located on the south bank of the Allegheny about six miles above the mouth of the river. Formerly the water was drawn directly from the river at this point; now it arrives at the station through pipes connected to the water purification plant located on the opposite bank in O'Hara township.

No emergency intakes is provided at the Brilliant station, whereby raw water may be admitted to the system.

The engines comprise four fifteen million gallon pumps, four twelve million gallon pumps and two ten million gallon pumps, equivalent to a combined capacity of one hundred and twenty-eight million gallons per twenty-four hours. Since the maximum daily pumpage is eighty-three million gallons, the reserve of forty-five million gallons is an apparent large margin. The effective margin, taking into account contemplated improvements and additions to the system, is nearer thirty million gallons. The engine room floor is above freshet line, but the boilers are in danger of being put out of commission by an extraordinary flood. Some corrective measures are planned and they are to be applied at an early date.

Highland reservoir number one has a storage capacity of one hundred and eighteen million gallons. Reservoir number two has a capacity of one hundred and twenty million gallons. The latter is ninety-one feet lower in elevation. Both are on the hill back from and near the pump house. Both are interchangeable, and both may be cut off and the supply be pumped directly into town.

River mud at times excessive. A large proportion of the heavier sediment has in the past been deposited in the reservoir. Some of the fine material found its way on into the street mains. Now that filtered water is being furnished, the city is engaged in cleaning out the service pipes and the reservoir preparatory to keeping them in such condition.

The distribution districts are divided into a low, high and extra high service.

The low service is a gravity supply from reservoir number two, but in emergencies or at choice it may be connected to reservoir number one. This territory comprises all the lower portion of the city bordering on the Allegheny and Monongahela

rivers—a strip not over one-half mile wide at any place. It includes the manufacturing, mercantile and down-town shopping districts. Probably one hundred and ten thousand people are served.

The high service comprising an extensive area with a resident population of ninety thousand people, is supplied by gravity from Highland reservoir number one. The district includes the lands too elevated to be properly reached by the low service.

The extra high service is furnished by water pumped from the high service mains into reservoirs and tanks located at such points and elevations as to serve districts above the reach of the high service system. There are four such services, named in order of importance, Herron, Bedford, Garfield and Lincoln.

A thirty-inch main from reservoir number one feeds the Herron pump station at the corner of Central Avenue and Craig Street in the central part of the city near Shenley Park. From this point the supply is pumped into the reservoir on Herron Hill, not far distant, and also by a separate main into the reservoir on Bedford Hill, near the down-town district. The latter basin holds two and a quarter million gallons and supplies a mercantile district of about twenty-seven thousand population. The former holds eight million gallons and supplies a large residential area of about forty-seven thousand population.

The Garfield tanks are of steel construction, hold five hundred thousand gallons and supply about ten thousand people resident near Highland Park. The pumping station is at the corner of Dearborn and Pacific Streets.

The Lincoln tanks hold two hundred and fifty thousand gallons, they are on the hillside near the east city line. The pump house is located on the corner of Park Avenue and Dean Street. There are resident in the district ten thousand people.

About seventy million gallons is the present average daily pumpage at the Brilliant Station.

PENNSYLVANIA WATER COMPANY.

The population within the city supplied by the Pennsylvania Water Company is about eleven thousand. All service connections are metered and the estimated consumption is about forty gallons per capita. On the municipal system it is between two hundred and thirty and two hundred and sixty gallons.

The company was chartered in eighteen hundred and eighty-seven to supply water in the township of Sterrett, out of which the Thirty-seventh Ward, formerly Brushton borough, and the Forty-first Ward, were made. The plant supplies Wilkensburg and other places as far south as North Braddock. In eighteen hundred and ninety-nine the Pennsylvania Water Company purchased the works of the Turtle Creek Valley Water Company, built to supply the boroughs in the Turtle Creek Valley, and then known as the East Pittsburg Water Company. The whole territory is now supplied from the pumping station of the Pennsylvania Water Company on the Allegheny river at Nadine. This point is about two miles above the Brilliant pumping station.

The water is taken from three filter cribs built three feet below the bottom of the river bed.

Crib number one is three hundred and eight feet long by thirty-three feet wide by five feet deep. It is covered with gravel and sand.

Cribs number two and three are each four hundred and eight feet long by forty-eight feet wide by five feet deep, built in the same way, cornerib fashion.

From number one crib a twenty-four-inch cast-iron pipe is laid below the bed of the river to a manhole on south bank of river. From cribs number two and three a forty-two-inch cast-iron pipe is laid below the bed of the river to same manhole; thence to the pump there is a six-foot tunnel. The bottom of the river over the cribs is not allowed to silt up. This is prevented by dragging over it a rake made of the pipe from which water is discharged in small jets under pressure of one hundred pounds per square inch. The observed reduction of bacteria in water pumped compared to the raw water is between ninety and ninety-nine per cent. when the cribs are in working order. Occasionally the cribs fall off in efficiency.

One ten-million gallon and one six-million gallon pumping engine raises the water to a reservoir of six million gallons capacity, located on high ground back of the station and distant therefrom five thousand feet. About twenty-three thousand feet from reservoir number one is reservoir number two, which holds twelve million gallons. They are connected by a forty-two-inch pipe. The portion of the city noted is supplied principally from reservoir number one, but Ward Thirty-seven may be supplied directly from reservoir number two.

The water furnished by the Pennsylvania Water Company is usually clear. It was generally superior in quality to that furnished by the city prior to the starting up of the Aspinwall filters.

MONONGAHELA WATER COMPANY.

As stated above, the "South Side," excepting Wards Thirty-eight, Forty-two, Forty-three and Forty-four, is supplied by the Monongahela Water Company. To meet the conditions imposed by broken topography, three services with reservoirs and tanks at different elevations have been installed by the company. They comprise the low district, the Allentown high district and the Esplen district.

The larger part of the supply is pumped from the Monongahela river at the main pumping station, situated on the river front at the foot of Twenty-ninth Street. The water is raised into the Birmingham settling basins, open brick-lined structures, built in the nearby hillside at the head of Thirty-first Street at the elevation of about two hundred feet above the river. These basins have a total capacity of three million gallons and from them the water flows by gravity to the low service area lying between the foothills and the river.

The intake is a thirty-six-inch pipe run out to the middle of the stream. There is a screen on the end of it. The power plant is subject to inundation. The pumps are not in first class order. There are five of them, one being four million, two being ten million and two being five million gallons capacity. The latter raise water five hundred and ninety-eight feet high through a twenty-inch line into three settling basins, each sixty feet in diameter by forty feet high, located in the Twenty-seventh Ward on the highest ground available in the Allentown district. Thirty-eight thousand people reside in the hill area—Wards Twenty-seven, Thirty-one, thirty-two and thirty-five—served by these tanks.

A sub-station, of not much account, at the Birmingham basins is maintained in reserve to pump water through a ten-inch pipe and by a cross connection into the twenty-inch line to the tanks.

The Allentown and the low service area comprising Wards Twenty-four to Thirty-five, inclusive, and Ward Thirty-six in the Esplen territory, constitute the "Old district" of the "South Side." Eighty-three thousand people are now resident therein. The daily consumption, excepting the Thirty-sixth Ward, approximates twelve millions gallons and the water is delivered through ninety miles of street mains. These mains are known to be clogged with mud deposit.

The new Esplen plant was built by the Monongahela Water Company and put in service in eighteen hundred and ninety-five. It is now operated in conjunction with the "Old district" works. Besides Ward Thirty-six, it includes the Thirty-ninth and Fortieth Wards (formerly Elliott and Esplen boroughs), and outside of the city, part of the borough of McKees Rocks and parts of Chartiers and Stowe townships.

The water is pumped from the Ohio river at a point opposite Brunot's Island. There are two filter cribs here sunk in the river bed from each of which a twenty-four-inch supply pipe leads to wells in the station. There are also fourteen twelve-inch drilled wells, each about fifty feet deep, from which water is drawn. The supply is lifted by two pumping engines, each three million gallons capacity, a vertical height of four hundred and twenty-five feet to two steel tanks, each fifty feet in diameter and seventy feet high, located on Sheraden Hill, from whence the discharge is by gravity to the district. Ward Thirty-six contains about four thousand people.

The superiority of the plans under municipal control in Pittsburg proper as compared with private ownership on the "South Side," above described, is partially conspicuous in every detail of design, management and maintenance, and is one reason for popular sentiment favorable to city ownership.

In December, nineteen hundred and six, the city petitioned for appraisement of the value of the plant and property of the Monongahela Water Company lying in Wards Twenty-four to Thirty-six, inclusive, since these were the city limits in eighteen hundred and eighty-five, when an agreement was entered into between the city and the water company, whereby the latter obtained an exclusive franchise for twenty-one years to the said territory of thirteen wards.

The company does not now own any pipes outside of the Twenty-fourth and Thirty-sixth wards, inclusive, excepting the pipe system connected with the Esplen plant, which lies largely outside the limits of the city. All others were purchased by the Chartiers Valley Water Company in eighteen hundred and ninety-six.

So the Monongahela Water Company will continue to exercise its franchises outside the "Old District," but still within Pittsburg's limits subsequent to any purchase of the "Old District" plant by the city.

In fixing upon a fair value for the plant to be purchased, the water company's experts have frankly admitted that improvements are advisable and necessary and would be made by any private individual accustomed to successful management of water works property. The quality of the water must be improved by filtration. The company's plans proposed as a basis for estimation of cost of giving good advice, is to locate a fifteen-million gallon filter plant at the Birmingham reservoir, build settling basins of approved type out of one of the existing basins and use the other to store filtered water; erect two new vertical pumps at the Twenty-ninth Street station to pump all the water needed from the river to the settling basins; provide a return pipe to remodeled high district pumps for delivery of filtered water to the Allentown tanks; build a new pump house and plant at the reservoir; raise up and alter the main station; clean out all street pipes; rebuild intakes, and, in fact, revamp the entire system to secure an up-to-date service.

At the present time there is no competition whatever in the supply of water in the district. There is a contract existing between the Monongahela Water Company and the South Pittsburg Water Company, the only other concern supplying water to adjacent territory, whereby these two companies refrain from entering into com-

petition. This should operate to the benefit of the service at once in the Esplen district and also in the thirteen wards in event of failure of the city to acquire the latter works.

It is the city's plan to supply filtered water should the "South Side" plant come under municipal control. The obligation of the water company is equally as great at all times to supply pure water at reasonable rates, subject to the regulation of the court.

SOUTH PITTSBURG WATER COMPANY.

The South Pittsburg Water plant comprises a pumping station on the Monongahela river at Beck's run, about one mile up stream from the Twenty-ninth Street station of the Monongahela Water Company, buried filter crib in the river bed and two auxiliary pipe lines leading directly from the stream into the pump well, a mechanical filter plant, including settling tanks, filters, clear water basin, chemical laboratories and all appurtenances of latest and most approved pattern, three five-million gallon service pumps at the filter plant to raise the water into a steel tank on the hill in Mt. Oliver borough and a system of distributing mains reaching a large population in the municipalities bordering the Pittsburg boundary and in the townships beyond. It is also serves the four hill wards of the city above mentioned. The works are managed with exemplary care under skilled direction. The water is clear and pure and the service is eminently satisfactory. This feature has materially aided in the building up of the district. A contract exists between the city and the company for fire hydrant service. All the territory covered by this water company and by the Pennsylvania Water Company will in likelihood, be annexed to Pittsburg, and following there is likely to be agitation for municipal control of the water works. Naturally city ownership would effect alterations in methods of distribution. Such possibility need only be thought of in considering the present question of supplying filtered water to the north and south sides of Pittsburg at present incorporated.

ALLEGHENY CITY.

The "North Side," formerly Allegheny City, is supplied entirely from water works owned and operated by the municipality, and like the other parts of Pittsburg, the topography is irregular, ranging six hundred feet or more in elevation, so that there are several systems of distribution.

The supply is taken from the Allegheny river at two points. At Montrose village in O'Hara township, opposite Verona, nine and a half miles up stream, is the principal pumping station. An auxiliary plant called River Avenue Station, is in the eastern part of the North Side at the site of the original pump house built in eighteen hundred and forty-nine.

Montrose intake has a timber crib twenty-five hundred feet long by thirty-two feet wide by seven feet deep, placed in a ten-inch excavation in the river bottom. It is planked on top and covered with gravel to original surface of the channel and its sides are riprapped filling. Difficulty has been experienced in keeping the structure open to admit of the passage of water. The sides have been dredged out for this purpose, but they fill up again. So far as keeping out silt from the pump chambers or clarifying the river water goes, the crib may as well be out of commission.

There are two fifteen million gallon triple expansion pumping engines and three twelve million gallon cross compound pumping engines in the station. They raise about forty million gallons of water daily a vertical height of two hundred and forty-seven feet through a sixty-inch steel force main nine and a half miles long to Troy Hill reservoir, where the water is delivered directly into the low service district without going into the reservoir. The surplus overflows into duplicate basins at said reservoir. The two large pumps are new. They were put in final commission early in the current year. Now all the supply is pumped at the Montrose station; but prior to nineteen hundred and seven for ten years or so about one-third of the water supply was drawn from the river at the River Avenue Station. Steam in one battery of boilers is still kept up at this old station in readiness for use during emergencies.

Here the intakes are two twenty-four inch and one thirty-six-inch pipes. They extend down stream for fifty-six feet and are perforated with one-inch holes. The plant is subject to possible interrruption of service at times of extreme high water. A combined rated capacity of thirty-three million gallons is afforded by the five pumps. They are in poor condition. The water is raised into Troy Hill reservoir nearby.

The Troy Hill reservoir holds seven million five hundred thousand gallons. It is of earth embankment construction, concrete lined and paved with brick. A wall divided the reservoir into two basins of about equal capacity. Each is in poor condition, especially at the frost line.

From Troy Hill reservoir the water was formerly furnished by gravity of the low service district, comprising a belt of varying width, extending nearly the whole length of the river front. The section includes all the manufacturing and commercial districts and covers an area of about two and a half square miles. The popu-

lation served approximates ninety-five thousand people. But not only the several distinct high services draw water from the basins. A thirty-inch and a sixteen-inch gravity main extends northeast about a mile to the Howard Street pumping station, which is located at the corner of Howard and Rising Main Streets. Here five pumping engines raise the water into tanks in districts B. C. and D. Each tank is forty feet in diameter and twenty-two feet high.

There is one eight million and one five million triple expansion pumping engine and one three million and two two million five hundred thousand gallon pumping engines of the combined duplex type in the station.

A twenty-four-inch main leads to two tanks on Nunnery Hill nearby. They are elevated two hundred and eighty-eight feet above the Troy reservoir. From them a residential area of one square mile, lying directly north of the low service district and comprising twenty-thousand people, is supplied by a gravity flow. This is high service district B.

A separate twenty-four-inch main also leads to two tanks, located eighty-five feet higher on Nunnery Hill, which feed district C, an area of two and seven-tenths square miles, extending to the northerly city boundary and containing an approximate population of twenty thousand people.

An irregular shaped area of one and two-tenths square miles adjacent to the eastern boundary of the city, containing a population of about ten thousand people, comprises high service district D. It is fed from two tanks on Spring Hill. A sixteen-inch force main from the Howard Street station delivers the water into these tanks. They are elevated about three hundred and sixty-nine feet above the Troy reservoir.

In district C at the city line is Green Tree Hill, the highest land in Allegheny county. On this eminence are two tanks supplied with water from an auxiliary pumping station on Broadway. The tanks feed a local extra high area of about two-tenths square miles. The pumps are electrically driven and have a capacity of one million gallons each. The consumption is small.

At the Troy Hill reservoir is a pumping station containing two pumps, rated capacity one million gallons each, which supply by direct pressure a district of about three-tenths square miles on the hill land in the vicinity.

The investigator must be struck with the lack in the water works of opportunity for sedimentation. Troy Hill reservoir has too little capacity to assure the removal of silt. Water of the quality of the Allegheny river, if delivered into the system without sedimentation or purification, is bound to clog up the pipes and house connections and reduce the efficiency of the works and hence increase the cost of operation and maintenance. These matters are indirectly prejudicial to public health.

WATER PURIFICATION PLANT.

Plans for a complete water purification plant large enough to furnish all of the city of Pittsburg, including the South Side, with pure water were adopted and construction work begun in nineteen hundred and five.

Opposite the Brilliant pumping station and just above it on the north bank of the river is a level plateau over a mile long and about half a mile wide whose elevation is higher than the highest freshet ever recorded. Here a slow sand filtration plant has been recorded, consisting of a pumping station, sedimentation basins, forty-six acres of covered filter beds, each an acre in area, covered filtered water basin and gravity supply mains under the river to the pump wells in the Brilliant station. The net daily capacity of the filters is one hundred million gallons based on a maximum rate of filtration of three million gallons per acre per twenty-four hours, making allowance for cleaning and other operations. The works were designed for future additions, space having been reserved therefor in the eastern portion of the tract owned by the city.

The site is in O'Hara township, bounded on the west by Aspinwall borough. At the upper end of the said tract are the new intakes and pumping station called Ross station. The capacity is between one hundred and forty million and one hundred and eighty million gallons per twenty-four hours, dependent on the height of river water. These engines raise the raw river water into the central receiving basin, capacity twenty million gallons, on either side of which are larger sedimentation basins, capacity sixty million gallons each, from which the water passes to the filters.

The heavier suspended matters deposit in the primary receiving basin. All three basins are designed to drain pumps leading to the drainage system of the plant.

The conduits carrying settled water from the basins lead to the central gate chamber at the primary receiving basin. The operation of the entire plant is controlled and directed at the administration building, erected over the central gate chamber. Here are the offices, rooms, operating mechanism and bacterological and chemical laboratories.

The sedimentation basins are at the foot of the hill. The filters lie between them and Freeport road and the tracks of the West Penn division of the Pennsylvania Railroad near the river bank.

Passing through the site of the filters is a right-of-way in which the sixty-inch Montrose station force main to the Troy Hill reservoir extends. This strip, sixteen feet wide, is laid out as a driveway and divided the filter layout into north

and south parts, three rows of filters being in each part. The distribution and collection system of pipes run at right angles to this driveway. The pipes are housed in covered galleries thirty-one feet wide in the clear, placed between alternate rows of filters. There are four of them, each about one thousand feet long, including the north and south part, and they contain all auxiliary apparatus and machinery for scraping, washing and restoring sand.

There is a fan-heating and ventilating system in each gallery to maintain a uniform temperature, also an attendant's room. A toilet room and locker and lunch room are provided in each half gallery. The floors of all of these places are made tight and arranged for ready cleaning.

Two sand washing tanks of concrete are placed in each half gallery. The flow of dirty water from the outlet weir of these washers passes directly into the drain. All the drainage is intercepted by a large main trunk drain along Freeport road, which empties into the river opposite gallery number one.

Adequate facilities for the treatment and disposal of the sewage created at the water filtration plant have been provided. Approval, according to law, was given in a permit issued by the Commissioner of Health under date of April, twenty-ninth, nineteen hundred and seven.

The filter beds have groined arched concrete floors and covers. The latter are carried on concrete piers fourteen feet on centers. The gravel underdrains total one foot in thickness, the sizes ranging from five to one and a half inches in diameter. The sand layer is between two and four feet deep. The underdrainage system consists of a concrete main collector extending the length of the filter in the longitudinal center bay and a lateral drain six to eighteen inches in diameter, in each transverse bay connects to this main collector. The latter has pipe connection to its corresponding regulating chamber, located in the gallery.

An automatic recording gauge, indicating the rate of filtration, loss of head and the depth of water over the sand, is supplied for each filter. The facilities for back-flooding the beds and for draining them and for the ordinary feed, are ample. Sand scraping and sand restoring machinery are used. However, the design permits of this work being done by hand were it necessary for any reason.

The filtered water conduit in each gallery connects with the main conduit ten feet four inches in diameter, extending to the filtered water reservoir. This structure is built of concrete, groin arched, width at one and two hundred and ninety-four feet, with a total length between the ends of eleven hundred and ninety-four feet, and holding forty-two million gallons. The roof is supported by piers twenty-one and five-tenths feet high, spaced eighteen feet apart on centers. The up-stream end is in line with the down-stream gallery of the filters.

The river side of the reservoir is nearly parallel and one hundred and twenty-five feet from the harbor line. Here an embankment has been filled in on a slope of two to one. The slope is protected up to the elevation of extreme floods with a heavy concrete revetment. A level berm twenty to forty feet in width is carried back from the top of the revetment to a second slope, rising to the level of the filling over the reservoir roof. Tile drainage and puddle cover have been provided to prevent percolation of surface waters into the filtered water basin.

There is an inlet and outlet chamber at the reservoir. An eighty-four-inch by-pass, laid on the reservoir floor, connects the two. The inflow may be measured by weir apparatus. The outflow is through two seventy-two-inch pipes, laid under the river to the pumping station at Brilliant. A place for a third seventy-two-inch pipe has been left. A ventrul meter is set up in each seventy-two-inch pipe. This is the last of four measuring stations by which the quality of water flowing from various parts of the plant may be observed and loss located.

In connection with distributing the filtered water a fifty-inch pipe line has been laid from Highland reservoir to a point on the north side of the Monongahela river, a distance of about five miles, and thence under the river by a thirty-six-inch pipe, to supply the "South Side." The thirty-six-inch main connects at Twenty-ninth Street with the system of the Monongahela Water Company, but water is not furnished, but might be in an emergency.

The general idea of the landscape treatment of the entire water filter layout is to isolate the site from surroundings by hedges and seed down the entire enclosure, lay out drives around and by the sedimentation basins, pump house and filters and reduce the formality of the view by shrubbery and small trees along the drives.

Three filters were put in commission in December last, seven in January, eight in March, six in April and three in May, and now there are altogether thirty-nine units operated. They are distributed along each of the four galleries. All of the water delivered through the Brilliant pumping station, as previously stated, comes from the purification plant; but not all is filtered. Only forty-one million gallons daily pass through the sand beds. The balance to make up the seventy million gallons daily consumption, more or less in Pittsburg, is water settled in the sedimentation basins. The two waters are mixed, since there is no way of keeping them separated.

If the thirty-nine filters were operated at their normal capacity, all of the seventy million gallons would be filtered. This result is to be accomplished as soon as possible. Fifteen men are now engaged in the operating galleries; they are distributed as follows: Two filter attendants for four galleries; two laborers for four galleries; one filter foreman; this makes a force of five men for four galleries for each shift of eight hours or fifteen men for each twenty-four hours. An additional

filter attendant and an additional filter laborer for each shift is to be put on. This will make twenty-seven men for each twenty-four hours instead of fifteen men. With this force the higher rates are to be attained as soon as possible without jeopardizing the entire plant.

In the cleaning operations there are now employed four machine operators, four filter laborers, two washer attendants and one machinist. This force is to be doubled. It has been found necesssary to do this to successfully work all the filters. Without adequate cleaning force, if the beds were run to their full capacity, it would tie up the entire plant. The unusually high turbidity of the Allegheny river this summer has retarded the development of the filters to their maximum efficiency.

In the laboratory work, whose results give the important index of necessary corrective measures in daily and hourly operation, there are now employed one analysist in charge, one assistant chemist, two laboratory assistants, two sample collectors and one laborer. Other help will be employed as required.

PROPOSED ADDITIONS.

The city asks approval of plans for the erection of ten additional filter units of the same size and form of construction as the existing filters, to be located up stream on the land belonging to the city and reserved for this purpose.

The annexation of Allegheny City has extended the territory and usefulness of the filtration works. The present plant has a maximum capacity of one hundred million gallons. The greatest consumption in Pittsburg as recorded is eighty-three million gallons. The Monongahela Water Company's district, if supplied by the city, will call for twelve million additional gallons of filtered water, making a total of ninety-five million gallons needed.

The "North Side" consumption is now forty thousand gallons daily; so it is evident that ten additional units are none too many. It is understood, however, that experiments with preliminary treatment are now in progress as a basis of design for materially increasing the capacity of the existing sand beds. This study of preliminary treatment is heartily recommended. The State Department of Health will be glad to favorably consider any well conceived method, thoroughly tested, with special reference to adaptability to local conditions.

The exigencies of the case, however, warrant no delay in providing for additional capacity, and the plans proposed for ten filters should be executed at once.

The city also proposes, as soon as money therefor shall have been provided, to add low service pumping machinery to the Ross pumping station and to build and equip a new high service pumping station at Aspinwall, for the purpose of delivering filtered water into the Allegheny mains; and when this has been done, to abandon the old River Avenue pumping station and also the Montrose pumping station.

Further, it is contemplated to build a reservoir of about one hundred million gallons capacity somewhere along the pipe line route to Allegheny.

Still further, in connection with the furnishing of filtered water to the "South Side" when the city takes over the works of the Monongahela Water Company, it proposes to abandon the use of the low service pumps at the Twenty-ninth Street station at once, and to deliver filtered water into the district mains. The filtered water supply will be lifted by the high service pumps at this station to the Allentown tanks, pending the building and equipment of new high service pumps and their installation in a new house to be erected at a site free from inundations or floods. Upon completion of this work the Twenty-ninth Street station will be entirely abandoned.

DISCUSSION.

The policy of the State in subserving the interests of public health bears a peculiar relationship to the endeavors of the authorities of Pittsburg along the same lines. The sewages of the municipalities situated on the banks of the Allegheny and Monongahela rivers above Pittsburg pollute to a very considerable and dangerous degree the waters which are the source of supply to all the districts hereinbefore described. Even the city's own sewage pollutes the water which passes over or by the intakes of the River Avenue, Twenty-ninth Street and Esplen pumping stations. To these facts have been attributed rightfully a considerable proportion of the typhoid fever cases and deaths of Allegheny county.

A circuit between the city, its environment and the country beyond its existency, no doubt, whereby infection is transmitted back and forth through the medium of water, milk and food stuffs. This circuit can only be cut when all of the drinking water in the city is pure water.

A compulsory proper disposal of household wastes of a poisonous nature at the farms and in the village is going along apace under State direction; but the compulsory discontinuance of the discharge of municipal sewage into the city's drinking water must necessarily require a long term of years for accomplishment. Meantime, the people must have pure water, and there is one law for all water works whether owned and operated by private or municipal corporation. The Pennsylvania Water

Company now has pending before the State Department of Health for approval, plans for improving its water supply which have a relation to the future development of the municipal system. The Monongahela Water Company, held up for the time being in making improvements, by the probability of having its plant partly taken away, must also provide adequate works to purify the water supply to its consumers and a decree to this effect will be issued.

It has been determined that the existing city water works will not be prejudicial to public health under certain conditions, and the same are hereby and herein approved and a permit granted for the proposed extensions, alterations and improvements, under the following conditions and stipulations:

FIRST: That this permit shall relate only to the water works now owned and operated or that may be owned and operated by the city between the territory now comprised within the boundaries of the city of Pittsburg as incorporated August first, nineteen hundred and eight. The acquirement of water works or extensions of water works by the city into any area beyond the said municipal territory of August first, nineteen hundred and eight, shall be made under the provisions of law requiring a written permit by the Commissioner of Health.

SECOND: That the city shall immediately upon its acquirement of the Monongahela Water Company's plant in the thirteen wards, fully inform the Commissioner of Health of the fact of the nature and terms of the agreement between the city and the water company, and the extent of the plant as acquired, more particularly in its bearing to any remaining property or works of the said water company within the city limits and similar information shall be given with regards to any acquirement of the Pennsylvania Water Company's plant in part by the city.

THIRD: That monthly reports of the operation of the water purification plant and of the water works system shall be filed in the office of the Commissioner of Health on forms satisfactory to said Commissioner. At the close of each season's work the city shall file satisfactory plans showing all additions, extensions and changes in the water works system made during the year, together with any other information in connection therewith that may be required.

FOURTH: That the city shall not later than December first, nineteen hundred and eleven, supply the "North Side" and the "South Side" and the old city proper, with filtered water and filtered water only. Provided, however, that if the Monongahela Water Company should not be acquired by the city then, in that event, the State Board of Health will require the said water company to filter the water supplied to all its consumers. And on or before December first, nineteen hundred and eleven, the abandonment of the Montrose and River Avenue pumping stations shall have been accomplished and also the Twenty-ninth Street station, if this latter property shall have been acquired by the city in time to admit of the changes in plans herein approved relative thereto being made, otherwise, a reasonable extension of time will be granted by the Commissioner of Health. It is the intent of this permit to bring about at the earliest practicable moment the elimination from the water works system of all emergency and other intakes whereby raw river water may be introduced into the distributing system.

FIFTH: That since greater filter capacity than that now possessed at the Aspinwall plant, together with the ten additional filter units is requisite to the furnishing of the entire city with filtered water. It is stipulated that tests of the preliminary treatment of the Allegheny river water shall be conducted by the city preparatory to the adoption of the best treatment, and that prior to installation of any permanent method, the plans therefor, together with the tests showing the adaptability of the process, shall be submitted to the Commissioner of Health for approval.

SIXTH: If at any time it shall appear that the water works system or any part thereof, or the water supplied to the public thereby is prejudicial to public health, then such remedial measures shall be adopted forthwith as the Commissioner of Health may approve or advise.

Harrisburg, Pa., August 17, 1908.

POTTSTOWN, MONTGOMERY COUNTY.

This application was made by the Pottstown Gas and Water Company, Pottstown, Montgomery county, and is for permission to extend its distributing main within its chartered territory and to install a water purification plant.

It appears that the borough of Pottstown, having a population of sixteen thousand, is a thriving manufacturing community on the north bank of the Schuylkill river in the southwest corner of Montgomery county.

The municipal territory is bounded on the west by West Pottsgrove township, on the north by said township and Upper and Lower Pottsgrove townships, on the east by the last named township, and on the south by the Schulykill river. Opposite the borough south of the river is North Coventry township in Chester county. Two highway bridges span the Schuylkill, connecting the scattered settlement along the south river bank on the flats called South Pottstown, where five hundred people reside, with the borough of Pottstown.

The incorporated area of about four square miles extends for three miles along the river. The topography is rolling, the surface drainage is fairly good, more especially since there are numerous natural water courses flowing to the river.

Manatawny creek is the principal stream. It enters the Schulykill in the western part of the borough. Its watershed is about seventy square square miles. A considerable number of the inhabitants live in dwellings connected by private sewers to the runs, which the borough has arched over to obviate a nuisance.

The principal industry is the manufacture of iron and steel. The plants are located along the lines of the Pennsylvania Railroad and the Philadelphia and Reading Railway, within fifteen hundred feet of the river. Two of them employ over a thousand or more hands and two others employ half as many. Twelve more concerns employ an average of about one hundred hands each. And among these are included hosiery mills, shirt factories and dye mills.

The Pottstown Gas and Water Company furnishes more water to the manufactories than to the citizens of the town. There are some private domestic wells, shallow dug. Their location is unknown to the Department.

The Pottstown Gas and Water Company was incorporated by special act of Assembly, April second, one thousand eight hundred and sixty-nine, for the purpose of making, raising and introducing into the borough of Pottstown a sufficient supply of gas and pure water. A subsequent act of May sixteenth, eighteen hundred and seventy-one, provided for the protection of the water company's mains and reservoirs. The company is now operated under the General Corporation Act.

The plant as first installed in eighteen hundred and sixty-nine had its intake to the Schuylkill river at the foot of Washington Street in the lower part of the borough, below the outlets of numerous sewers. In eighteen hundred and ninety a new pumping station and river intake were built up stream about one mile beyond the borough line at the village of Bramcote in West Pottsgrove township. The old station and intake were abandoned. The new intake is the one at present in use.

Said intake consists of a thirty-inch cast-iron pipe, extending into the river sixty feet from low water line, the river here being about three hundred feet wide. At low water the outer end of the intake is in a pool four feet deep. The shore end of the pipe terminates in a screen well five feet in diameter, located on the bank of the river. The water thence flows by gravity through a brick tunnel four or five feet into a pump well, which is said to be twelve feet in diameter and twenty feet deep. It is two hundred feet back from the river bank adjacent to the pump house.

The pumping machinery consists of two horizontal compound condensing engines, one a Barr pump, rated capacity, three million gallons, and the other a Worthington pump, capacity, one and a half million gallons per twenty-four hours. By these engines water is raised to a twenty-four-inch cast-iron force main, one and a half miles, to a five million gallon reservoir on Stowe Hill, north of the borough in West Pottsgrove township. It is reported that the average vertical lift is one hundred and sixty-three and five-tenths feet, not including friction.

The storage reservoir on Stowe Hill is approximately two hundred by three hundred feet in plan and thirteen feet deep. The side walls are of stone masonry, plumb on the inside. The bottom is concrete. A partition wall six feet high divides the reservoir transversly into north and south basins. Ordinarily the water is pumped into the northwest corner of the reservoir and taken out at the southeastern corner, both inlet and outlet pipes being flush with the bottom. However, the piping will admit of water being supplied and drawn from either basin independently, so that six feet of water may be maintained on one side of the partition wall while the basin on the other side is being cleaned. There are no plans filed in the Department of the details of any part of the water works system. How the reservoir is drained the Commissioner of Health does not know. There is a by-pass by means of which water may be forced directly into the town street pipe system without first passing through the reservoir.

From the Stowe Hill reservoir there is a twenty-inch gravity main to town which furnishes the distribution system. It extends easterly through the borough in Berks and King Streets, a total distance from Stowe Hill of about two miles to Washington Street. In this highway there is a ten-inch pipe extending northerly about half a mile to a one and a half million gallon reservoir on Washington Hill. It is in the borough and is elevated about one hundred and fifty feet above the river. This small reservoir was a part of the plant as first installed in eighteen hundred and sixty-nine when the intake was at the foot of Washington Street.

This reservoir takes the overflow from the system. It is irregular in shape and seventeen feet deep. The inner slopes are paved with brick and the bottom is concrete. A float valve regulates the inflow, shutting it off at a predetermined elevation.

The average consumption is said to be one million six hundred thousand gallons daily of which one million are furnished for industrial purposes. In summer the consumption is two million gallons per twenty-four hours. Thus the storage capacity of both reservoirs at six and one-half million gallons permits the pumps to be shut down for three or four days without a curtailment of use of water in the district. The company selects the most suitable time for pumping from the river. The first waters of a flood being most turbid are permitted to pass. The pumping station was under six feet of water and out of commission for a period of three days in February, nineteen hundred and two, and this may occur again at any time. The company reports that about four thousand people living in the borough do not take public water but derive their supply from shallow wells. There are said to be many hundred loose vault privies in the town.

The records filed in the State Department by the local authorities show that there were in Pottstown the following number of typhoid fever cases: for nineteen hundred and six, thirty-five; for nineteen hundred and seven, forty-eight, and for nineteen hundred and eight, up to and including April, thirty-three cases.

At the Hill School in December, nineteen hundred and three, and the following month, there was an epidemic of typhoid fever, which is said to have been due to infiltration from a cesspool into the well which supplied the drinking water. This well has since been closed up and the school now receives its supply from the water company.

The water company also furnishes water to the public in the townships of West Pottsgrove and North Coventry.

The supply main to North Coventry is carried across the river at Hanover Street and furnishes a supply to about one hundred inhabitants. The West Pottsgrove township district comprises the outskirts of the borough and there are about four hundred individuals here to take the water, so it is reported. The charter right granted the company is for the borough of Pottstown only. There is no record in the office of the Secretary of the Commonwealth of the water company having secured the franchise or right to extend its water pipes beyond the limits of Pottstown borough.

Under act number one hundred and seventy-seven, approved May twenty-first, nineteen hundred and one, the company might have legally supplied water to the settlement surrounding Pottstown, but if water is being furnished there by the Pottstown Gas and Water Company in compliance with a petition from the owners of a majority of the land in these districts, the records in the office of the Secretary of the Commonwealth do not show it. Hence it would appear that the said company has no legal right to furnish water beyond the limits of Pottstown.

The application of July twenty-seventh, nineteen hundred and seven, to extend distributing pipes in North Coventry township and West Pottsgrove township cannot be acted upon by the Commissioner of Health until the water company shall have obtained a charter right to supply water to the public in these townships. consequently, a withholding of approval of the pipes already laid in these townships and used to supply water to the public therein by the Pottstown Gas and Water Company on the date of its application of July twenty-seventh, nineteen hundred and seven, must be decreed by the Commissioner of Health.

The extension of distributing pipes in the borough may be approved, but until the company shall have submitted a plan of the piping system showing dead ends and drained facilities among other things, the Commissioner of Health cannot be in a postion to act most intelligently with respect to particular stipulations in relation thereto.

Rapid sand filtration preceded by coagulation and sedimentation is contemplated in the plans for the proposed water purification plant submitted for approval. The plant is to be equipped under a guarantee by the New York Continental Jewell Filtration Company. The concrete work is to be constructed by the water company.

The filter plant is to have a capacity of four million gallons per twenty-four hours. However, it is the intention not to operate it more than twelve hours or so daily. It is to be located immediately north of the present pumping station. The filters will be housed in a reinforced concrete building one hundred and forty feet long by fifty-two feet wide. In the end nearest the pump house will be the sedimentation basins and in the other ends the filters, and below them the clear water basin.

Two centrifugal pumps, each five million gallons capacity, are to be set up in the pump house and used to raise raw water from the pump well into the inlet chamber of the sedimentation basin, extending from the bottom seventeen feet eight inches high. The water will rise in this chamber which will be about four square feet and pass out through two ports controlled by gates, one on either side to the inlet weir trough extending across the entire end of each basin at the top. A longitudinal wall will divide the entire tank into equal halves. Adjacent to the inlet chamber is to be an overflow chamber extending from top to bottom in the line of the division wall. It will connect with the sewer and will be provided with ports to drain out each basin when necessary. The top of the overflow chamber will be five inches above the inlet weir. Passing over this weir the water will flow in either chamber under a baffle board extending from the roof nearly to the bottom. Both basins together to a depth of sixteen feet ten inches will afford a period of sedimentation of about three and one-half hours when the plant is being operated at the rate of four million gallons per twenty-four hours.

The outflow from the basin is to be over weirs into collecting troughs extending the full width of the basins at the end nearest the filters. This weir or dam will be eight inches lower than the top of the overflow chamber at the opposite end of the basin.

Over the outlet end is to be the chemical room and coagulant solution tank. Sulphate of alumina is to be used and the solution will be applied in the pump well. The amount of solution to be used will be regulated by an orifice box to be placed at a convenient point at the pump station.

The elevation of the bottom of the sedimentation basin is to be on a level with the engine room floor.

The last forty-two feet of the purification plant is to be devoted to clear water basins and the filters. This basin will be four feet deeper than the sedimentation basins. A twenty-four inch influent pipe from the collecting trough at the outlet end of the sedimentation basin is to extend in the adjacent operating gallery of the filter house. This pipe will reduce to twenty inches and fourteen inches in diameter and from it will lead ten inch pipes on either side to the filtering units of which there are to be three in each row. Each filter unit is to have a surface thirteen feet by seventeen feet ten inches and its capacity is to be two-thirds of a million gallons per twenty-four hours when operated at the normal rate of the plant. The ten inch inlet pipe is to discharge into a chamber at the head of the filter out of which at the top are to extend three iron gutters across the full length of the filter. Their tops are to be twelve inches above the sand surface.

The mainfold system on the bottom of each filter unit is to consist of a six inch cast iron pipe off of which is to be taken in parallel rows, six inches on centers one and a half inch wrought iron pipes fitted with strainers six inches on centers. Over this collecting system, which is to be imbedded in the concrete floor of the unit flush with the bottom of the strainers is to be laid nine inches of gravel supporting twenty-seven inches of sand. An eight inch effluent pipe will conduct the filtered water to the central pipe gallery and rate controller, whence the water will go to the clear basin below. The arrangement of valves and piping is such that the wash water will be wasted to the sewer and also the first filtered water. The wash water will be taken from the pressure main.

The aim in the design is to maintain practically the same level on the filters as that of the water in the sedimentation basin. The overflow weir in the latter structures will prevent overflowing of the filters. Besides a device operated by floats influenced by the level in the sedimentation basin will operate to reduce the speed of the pumping engines. This will obviate the wasting of any water. the air wash is to be accompanied through the water manifold system. Each filter unit is to be provided with the regulation loss of head gage. The effluent controllers are to be of the Weston type. A free air discharge of filtered water in the clear water basin below is to be maintained.

At the bottom of the inlet chamber of each filter is to be a ten inch connection with a twelve inch sewer in the central gallery. This sewer will extend through said gallery and thence longitudinally through one of the sedimentation basins near the central wall to the overflow chamber where it will discharge in the bottom of said chamber.

The material excavated from the hillside where the purification plant is to be erected is being used to form a dyke about the pumping station to keep out floods. The water will rise in the overflow chamber, backing up through the sewer from the river and will attain a level possibly seven feet above the chamber during some extraordinary freshet. At such times it will still be possible to wash the filter and drain the dirty water to the river.

The entire form of construction of the basins and filters is to be reinforced concrete. The sedimentation basins are to have flat roofs of concrete construction. The operating gallery and inlet ends of the filters are to be housed over in the customary manner by a concrete or brick superstructure and the chemical store house will be of the same type.

The operating gallery will be covered by a platform of concrete made water tight.

Beneath the filters and the gallery is to be the clear water basin. It will occupy the entire space, being thirty-nine feet eight inches by forty-nine feet four inches in plan and having a depth below the under side of the floor of the pipe gallery of seven feet five inches. Its capacity will be about one hundred thousand gallons.

The existing pumping engines of the town service are to have their suctions connected to a twenty-four inch pipe terminating in the clear water basin, but the old suction pipes to the raw river pump well are not to be disconnected. Valves are to be placed on them and they are to be kept for emergency uses.

In view of the foregoing considerations it has been determined that a permit be withheld and it is hereby and herein withheld from the Pottstown Gas and Water Company to supply water to the public in the townships of North Coventry and West Pottsgrove until said company shall have obtained legal right so to do.

It has also been determined that the water works system and the source of supply and the extension of water pipes in the borough of Pottstown will not be prejudicial to public health and the plans therefor are hereby and herein approved, also the plans for the water purification plant hereinbefore described and a permit is issued therefor and for the extension of the mains in the streets of the borough under the following conditions and stipulations:

FIRST: That complete plans of the intake, pump well, pumping station, purification plant, showing the plant as it is constructed with all appliances and appurtenances, valves, etc.; and that complete plans and elevations of the force main, distributing pipes, gates, hydrants, blow-offs and drainage facilities, shall be prepared; and that plans and elevations of the distributing reservoirs shall be prepared by said company, and all of said plans shall be filed in the office

of the Commissioner of Health on or before the first day of January, nineteen hundred and nine. At the close of each season's work the company shall file a plan of the pipe laid during the year in the office of the Commissioner of Health, together with such other information that may be required to the end that the Department shall always be fully informed of the extent of the water works system and its use.

SECOND: The filter plant shall be operated for one year under the responsible direction of the experts who have designed it or by some other expert equally competent to render this service. A full report of the intial test of the proposed filters shall be submitted to the Commissioner of Health and thereafter the water company shall assist the State Department of Health in making such tests of the plant from time to time as may be found desirable. If necessary the Commissioner of Health may prescribe the standard of efficiency and make regulations for the operation and maintenance of the plant and the water works system, so far as the interests of the public health may be concerned.

THIRD. Weekly reports of the operation of the water works system and purification plant shall be kept on blank forms satisfactory to the Department of Health and copies thereof shall be filed with said State Department. If at any time, in the opinion of the Commissioner of Health, the water works system or any part thereof, or any water furnished thereby has become prejudicial to public health, or inefficient or defective, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve. The introduction of raw river water into the street system is absolutely prohibited with this exception. The gates on the river suction pipe shall be kept closed and sealed under arrangement satisfactory to the Commissioner of Health and only in some great emergency fully justifying the use shall these valves be opened and the raw river water be pumped into the system. In such an event the public shall be immediately warned of the fact and the local and State Health authorities shall be notified.

FOURTH: The drainage from the purification works shall, if ever required by the Commissioner, be otherwise disposed of than into the river.

Harrisburg, Pa., July 15, 1908.

RETREAT, LUZERNE COUNTY.

Central Poor District.

This application was made by the Board of Directors of the Central Poor District of Luzerne County, Pennsylvania, and is for approval of preliminary plans for an additional source of supply to the institutional buildings.

Under the Act of the General Assembly, number two hundred and eighty-eight, approved June sixth, nineteen hundred and seven, entitled "An Act to authorize all State Hospitals for Injured Persons, and all hospitals for the care and treatment of the insane, in whole or in part maintained by State aid, to acquire land for hospital purposes; and to take waters, streams, lands, properties and materials for the purpose of supplying said hospitals with pure water for hospital purposes; prescribing the manner in which said lands, streams, property and materials may be taken and the manner of compensating the owners thereof for such taking," the Directors of the Central Poor District of Luzerne County have given notice to the Commissioner of Health of their intention to obtain a new source of supply of water to said Institution. The said Act requires a compliance with the Purity Water Bill, so called, approved April twenty-second, nineteen hundred and five, and still further provides,

"That no waters shall be condemned and appropriated under the provisions of this Act, nor any water system, reservoir, pipe or conduit be constructed or maintained, until a permit for the condemnation and appropriation of such waters, or the construction or maintenance of such water system, reservoir, pipe or conduit, shall have been procured from the Department of Health and the Water Supply Commission of Pennsylvania."

It appears that the Hospital for the Insane and also the almshouse for the Central Poor District of Luzerne County are located at Retreat, a railroad station on the Sunbury Division of the Pennsylvania Railroad, twelve miles southwest of Wilkes-Barre. The grounds comprise about one hundred and fifty-five acres, which extend along the south bank of the North Branch of the Susquehanna River for about one and six-tenths miles and back therefrom about one-quarter of a mile. This tract is located at the foot of the mountains and contains about fifty-five acres of land under cultivation, which stretches along the flats and is from twenty to twenty-five feet above the river level, ordinary stage. The railroad tracks are built along one side of the flats and south of them the land rises to the foothills. The immediate site of the buildings is on a shelf of ground elevated about one hundred feet above the river.

The almshouse buildings comprise two poor houses, one for male and one for females, the superintendent's home and barn and out structures. They were erected about eighteen hundred and seventy and occupy the westerly portion of the ground.

The insane hospital buildings were constructed about nineteen hundred and additions have since been made. At present there is the four-story administration building with three-story wings on either side for the male and female wards and in the rear is the power house, the cold storage building and the morgue.

The administration building is heated by direct steam but the other buildings are provided with the hot air introduced by means of blowers operated at the power house.

Patients from Schuylkill, Carbon and Luzerne County are received at the Institution. The insane department, accommodates about five hundred patients and requires sixty employes. The almshouse accommodates about three hundred patients and employes, making a total of about nine hundred people at the institution

Sewers were first installed in eighteen hundred and ninety-eight, they take both sewage and storm water. The main sewer is twenty-four inches in diameter, serves the almshouse buildings and some of the hospital buildings. It passes under the railroad tracks west of the depot and receives a connection from the depot. The point of discharge is into the river about opposite and slightly up stream from the pump well from which the Institution's water supply is drawn. There is an eighteen inch sewer pipe extending from the north wing of the insane hospital northerly under the railroad tracks and thence along the flats about nine hundred feet westerly to the twenty-four inch sewer into which it discharges.

With the exception of the depot, the buildings of the institution are elevated sufficiently to admit of a gravity discharge of sewage to works which might be provided for the purification of the sewage.

The well from which the Institution's water supply is taken is located in the porous ground on the flats between the railroad and the river. It is three hundred feet back from the river bank and about one hundred and fifty feet from the railroad. The well is thirteen feet in diameter, twenty-seven and five-tenths feet deep, lined with brick and covered with a concrete roof provided with a manhole for inspection.

On July sixteenth, nineteen hundred and seven, the date of the Department's inspection, there was four and one-half feet of water in the well, the surface of the water standing two feet below the level of the river water level.

During the summer months the water is frequently drawn down to within one foot of the bottom of the well, making it necessary to run the pumps very slowly during the entire twenty-four hours to avoid uncovering the suction pipe.

Originally the pump house was located over the well, but in the spring of nineteen hundred and three, it was carried away by ice. This was the year of the noted ice gorge, when many structures went down all along the entire length of the Susquehanna River. That water at the time stood thirteen feet above the top of the present roof of the well. A new pump house was constructed on the river side of the railroad opposite the boiler house.

It is a one-story brick building, built over the concrete pump well in the bottom of which well are the two duplex pumping engines, having each a maximum capacity of two hundred thousand gallons per twenty-four hours. The top of this well is three and one-half feet above the high water mark of the freshet of nineteen hundred and three. The floor of the well is twenty-five feet below the top of the sides. From the bottom there is a concrete gallery four feet high and two feet wide extending to the well, in which gallery is laid the eight inch suction pipe. The pumps are so arranged that one may be used to keep the pump well dry during high water stages of the river.

The steam is supplied from the boiler house on the opposite of the railroad.

There is a tank reservoir located on the mountain side about eight hundred feet in the rear of the administration building. It is twenty feet high and is reported to have a storage capacity of one hundred thousand gallons. It is not in a good state of repair. The top of the tank is two hundred and seventy feet deep above the pumps and one hundred and twenty feet above the roof of the highest building at the in stitution. There is a six inch force main extending from the pumps to the tank. It is possible to pump directly into the distributing pipe system whenever this may be desired. It is estimated that there are about three thousand feet of six inch pipe in the ground including the force main. Nine fire hydrants are connected to the six inch fire supply line in the grounds and there are various small pipes attached to standpipes in the buildings, making a grand total, so it is reported, of thirty-three hose connections on the ground.

The main well water is said to be acid to an extent sufficient to require constant repairs to the hot water heating system. Large amounts of iron are precipitated and water drawn from hot water spigots is always red in color. It is further reported that when ever the river water overflows the well there follows an epidemic of enteric diseases at the Institution.

Besides having an effect on the hot water flushing and boiler tubes, which makes a pure supply desirable, the quantity is inadequate during the summer months. The directors wish to secure an abundant supply ample for all fire protection as well as domestic consumption.

When the river well is flooded recourse is had for drinking water to a supply from a bore hole extending seven hundred feet horizontally into the mountain. This source is unreliable and sometimes disappears completely. There is also a spring house at the foot of the mountain beyond the female pauper building. The quantity of water here is small and it is used only at the piggery.

Daily consumption of water at the Institution is about one hundred and fifty thousand gallons.

The petitioners purpose to obtain the new source of supply from the surface streams located on the opposite side of the river and forming tributaries of the east branch of Hunlocks Creek. The main stream by this name empties into the Sus-

quehanna River about one mile and a half above Retreat. The east branch affords the site of the proposed reservoir. It is just below the forks of the two tributaries. The stream to the east being known as Peg Hunter Creek and the one to the west being known as Hughes Creek.

Peg Hunter Creek has a watershed of three square miles rather precipitous and about three-quarters wooded. There are nine farm houses on the area. Its easterly branch rises in springs and is in woodland excepting one farm. The water has excellent appearances. Its northern branch rises in Mud Pond, so called, lying at the head of the valley, surrounded by hills and formed by a low sand-stone ridge. The pond has an area of about twenty-four acres, an average depth of ten feet of water and soundings failed to reveal the depth of the mud. The latter is known to be twenty-five feet deep. Evidently this body of water is fed by springs, the water is cloudy in appearance, has a fishy taste and the shores are surrounded with a strip of luxuriant water plants. There is no economical way of draining this pond or of reclaiming it.

Hughes Creek has a watershed of two and seven-tenths square miles, three-fourths of which is farm land, the balance being wooded. There are sixteen farm houses on it drainage area.

Above where it is proposed to construct a dam below the forks of the two creeks, the watershed has an area of about five and seven-tenths square miles. The average dry weather flow is estimated at three hundred and forty thousand gallons per day. The twenty-six farm dwellings with accompanying outbuildings, together with the mud pond, form the only sources of pollution.

The new reservoir proposed is to be formed at the site of an abandoned dam. The petitioners have two plans under consideration. One is for the erection of a dam twenty feet high with the crest five feet above water level and a length of three hundred feet. This structure would flood six and four-tenths acres and give a storage of about eleven million gallons. The other plan calls for a dam ten feet higher by which nineteen acres would be flooded and a storage capacity obtained of about forty-six million gallons.

Either reservoir would extend back a short distance up each tributary. The reservoir site is composed of bottom land with some swamp. There is also a group of farm buildings near the flow line. It is reported that solid rock foundations may be secured upon which to rest the dam. An earth dam with concrete core wall and spillway has been suggested and that the lower dam be built first in conformity with plans by which the ten additional feet may be put on without endangering the structure in the future. However, detail plans have not yet been prepared. It is proposed to conduct the water from this reservoir by means of a six inch or eight inch pipe line which will follow the course of the creek to the Susquehanna River, thence diagonally across the river to a point about opposite the northerly end of the Institution grounds, thence parallel with the railroad to the present pumping plant where it is to connect with the present system.

The elevation of flow line of the reservoir, lower level is two hundred and fifty-seven feet above the pumps.

It is proposed to construct a reinforced concrete reservoir on the hill in the rear of the Institution Its capacity is to be about five hundred thousand gallons. The water from the storage reservoir at the source will flow by gravity to the distributing reservoir in the rear of the Institution.

The Department is unable to say, without going into an examination of local territory more thoroughly than it seems to be the province of an advisory power, whether the site selected for the dam is the very best one possible. The watershed, however, is sparsely populated and the purity of the waters can be safeguarded as easily as the waters from any territory available for the Institution.

The directors should consider this possible necessity of cutting out Mud Pond water. This would be done by digging open trenches following the contours about the pond by means of which the upland waters would be intercepted and delivered into the stream below the pond. Such a remedy might be resorted to in case the entire creek supply became impregnated with objectionable odors and impurities, imparting a disagreeable taste to the waters which could not otherwise and at less expense be eradicated.

A sanitary patrol should of course be maintained to secure the proper disposition of sewage on the contributing area above the dam.

The directors should also take into account the probable deterioration in water stored in the reservoir and attributable to shallow flowage. It is good practice where filtration of the surface waters is not to be accomplished to remove from the bottom of a reservoir all soil and mud and organic matter, especially in that portion to be flooded to a shallow depth. And it is also good practice where money can be secured therefor to eliminate shallow flowage by the excavation of earth around the edges and the depositing of it at the shore line, equalizing the cut and fill in such a way as to secure the greatest benefits for the outlay and effect as great a depth of water at the shore line as may be practicable. However, there should be a reasonable limitation of this kind of work.

The surest remedy of all is the filtration of a surface water supply and probably the time will come when all such supplies derived from inhabited areas will be filtered.

The minimum yield of the five and seven-tenths square miles of watershed without storage, based on measurements of a neighboring stream is estimated at one hundred and eighty thousand gallons per twenty-four hours. The maximum con-

sumption for the future at the Institution is taken at three hundred thousand gallons daily, or one hundred and twenty thousand gallons in excess of the daily minimum flow of the stream. So the proposed storage reservoir at the low level would, together with the minimum flow of the stream provide an hundred day's supply to the Institution at the expiration of which the storage would be depleted. This is believed to be a sufficient storage. But having in mind the possibility of an Institutional growth, not now anticipated, and an even greater consumption of water than estimated, it would be prudent for the directors to plan the dam and the reservoir to admit of its safe enlargement should this ever become necessary or desirable.

A six inch supply main from the dam to the pump house is impracticable. The friction in this length would limit a pipe of this diameter to a total discharging capacity in twenty-four hours of about five hundred thousand gallons. The demand for fire service at any time might be greater than this. It should be possible to easily obtain through the supply main enough water to furnish three good fire streams of three hundred gallons per minute each. The elevation of the proposed dam is seven hundred and sixty-five feet. When the water is drained off for cleaning purposes, the flow of the stream would be taken into the gate house at an elevation of fifteen feet below this point. From this lower elevation an eight inch pipe could not deliver nine hundred gallons per minute to the pump house, and neither could it do so if the reservoir were full, but a ten inch pipe would be ample in size.

The advantage of a ten inch supply main still further appears when it is made clear that the loss of head through it in delivering the average daily consumption to the Institution of three hundred thousand gallons would be but six feet, while if an eight inch pipe it would be at least twenty feet. In other words the high water mark in the proposed distributing reservoir to be erected on the hillside back of the Institution cannot be placed higher than elevation seven hundred and forty-four if the ten inch pipe be used, while it would be fourteen feet lower if the eight inch pipe were used. The difference in cost of about five thousand dollars would seem to be wholly in favor of the ten inch line.

Elevation seven hundred and forty-four is eighty-four feet only above the highest roof at the Institution. The present tank is one hundred and twenty feet above such roof. It is desirable that the reservoir should be as high as possible and permit water to reach it by gravity from the dam. While elevation seven hundred and forty-four will give a good domestic pressure, in case of fire, pumping engines must be relied upon for service.

In view of the foregoing consideration, approval is given to the general plan under the conditions that the directors prepare their detail plans along the lines herein suggested and submit the same to the Department of Health for final approval. Also that ample provision should be made at the dam for the complete drainage of the reservoir, and adequate drainage facilities along the line of the gravity main and of the entire water works system shall be provided. The possibility of an ultimate filtration plant on the hill in the rear of the Institution shall be taken into account in laying out the distributing reservoir.

The directors should anticipate the construction of a sewage purification plant at no distant date and prepare plans therefor, and submit the same to the Department of Health for approval at as early a date as convenient.

Harrisburg, Pa., February 27th, 1908.

RICHLAND TOWNSHIP, CLARION COUNTY.

Foxburg Water Works Company.

This application was made by the Foxburg Water Works Company, Richland Township, Clarion County, and is for permission to install an additional source of supply to the public in its charter district.

Foxburg village is located in the western part of Clarion County in the southwestern part of Richland Township, and is on the eastern bank of the Allegheny River, just above the mouth of the Clarion River. There are no industries and but a few citizens. The population to-day is not as great as it was twenty years ago. In nineteen hundred it was six hundred and forty. The land in the village is all owned by the Fox Estate and the dwellings have been erected on lots leased of the Fox Estate. The region round about is productive of oil and the people who live in the village are principally dependent upon the oil industry. The branch of the Baltimore and Ohio Railroad which extends from Kane to Pittsburg, passes over the Allegheny at this point. The Pennsylvania Railroad extends along the river bank in the borough. The particular reason why individuals have been willing to erect houses on leased land in preference to taking up residence at other places in the oil region is because the Fox Estate has been willing, at its own cost and expense, to make public improvements, which has somewhat lessened the cost of living in the village. For instance the sewers have been provided by said estate and the water works system was established and is being maintained by said estate without profit.

The ground ascends rapidly from the river to the crest of the mountain, distant a quarter of a mile and elevated several hundred feet and the village is located on the hillside and on the narrow flats at the foot of the slope. On the other side of the mountain crest the land descends as rapidly to the Clarion River. The highways follow generally the contour.

The Foxburg Water Works Company was incorporated and the plant installed in eighteen hundred and seventy-seven and it has furnished water to the inhabitants of the village, drawing the supply from the Allegheny River until recently. Above the railroad bridge across the river there is an intake crib in the bed of the stream near the east bank, covered over with sand and gravel to a depth of about four feet. The river water was drawn through this filter and raised by two steam pumps to two wooden tanks located on the hill two hundred and eleven feet above the river, each tank holding about fifty thousand gallons. From the tanks the water was conveyed by four inch and three inch branches laid in the streets of the village to the various points for consumption and for fire protection.

The wooden tanks were found to be in such a state of decay and the river water, being contaminated by the sewage of places above on the Allegheny River, being considered dangerous, the owners of the water works determined it to be in the interests of public health to entirely abandon the river source and to seek a new supply of drinking water and this was done.

On the day of the Department's inspection in October, nineteen hundred and seven, the old water works plant was being maintained for fire protection only. A new water works system and new source of supply was found to be in use. The approval of this new plant is the subject of the application herein considered.

On the crest of the mountain immediately back of the village four six inch wells have been sunk to a depth of one hundred and fifty feet. There is a level tract of ground which may be considered the surface watershed in which the wells are located. Possibly it comprises one hundred acres, all owned by the Fox Estate and unoccupied. The geological structure encountered in drilling the wells was sand rock and shale. The water is obtained from the sand rock at a depth of about one hundred and forty feet below the mountain crest and at a height of about one hundred and forty feet above the river. A very satisfactory quality of water is yielded from this strata.

Each well is cased off in the customary manner and the water is raised therefrom by a natural gas engine. The pumping arrangement is similar to the ordinary method employed at oil wells. Each well is tubed and near the bottom is placed a working barrel from which rods extend to the surface and there connected with horizontal "sucker" rods extending to the power house located in the middle of the space on the circumference of which are the wells. In this way one engine is adapted to the working of lifting the water from each well.

The water is delivered into an open concrete and masonry storage reservoir built near the wells. This structure is retangular, one hundred and five feet long and seventy-three feet wide on top, with sloping sides, with a depth of fourteen feet. Its capacity is about three hundred and ninety thousand gallons. The reservoir is provided with an overflow pipe and a drainage pipe. The top of the wall extends several feet above the surrounding ground and iron posts imbedded therein support a wire screen fence.

The water is conducted from the reservoir to the village in a four inch cast iron pipe and the lateral mains have diameters ranging from two inches to four inches. Blow-offs are located at dead-ends.

It has been ascertained that each well can deliver twenty thousand gallons of water per twenty-four hours or a total daily capacity of eight thousand gallons. There are a very few domestic wells or springs in the village. There are at least five hundred water consumers and the maximum consumption is forty thousand gallons. It would appear, therefore, that the company has secured an ample and pure supply of drinking water.

The fire service water mains are entirely separate from the domestic water lines. There are the old pipes used formerly in connection with the river supply. It is the purpose of the petitioners to continue the maintenance of the old pumping station for the fire service. By means of a valve the two systems may be connected and hence in case of accident or emergency the reservoir water may used for fire protection or the river water may be used for domestic consumption. The systems are interchangeable. However, the water works are not conducted by the Fox Estate as an investment for profit and the likelihood of the river water being introduced into the drinking water pipes is extremely remote. Nevertheless, Foxburg is one of the places along the Allegheny River where public health is menaced by the discharge into the river of sewage from municipalities higher up on the watershed.

Should there be any material increase in the village population, requiring the obtaining of a large supply of water, it is probable that the Allegheny River might be the ultimate source and this is one of the many reasons why the purity of upland waters should be preserved as a public asset.

It has been determined that the proposed water works system and source of supply is not prejudicial to the public health and the same is herein and hereby approved and a permit granted therefor under the following conditions and stipulations:

FIRST: That at the end of each season a plan of water pipes laid during the year shall be prepared and filed in the office of the State Department of Health, together with any other information in connection with the water works that may be required, in order that the Commissioner of Health may at all times be fully advised of the extent of the water works system and the number of people who are supplied with such water.

SECOND: If at any time in the opinion of the Commissioner of Health the source of supply or the water works or any part thereof shall have become prejudicial to the public health then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

THIRD: Allegheny River water shall not be introduced through the fire protection pumping plant and street mains or by any other means into the domestic water works sytem except under some great emergency and not then unless the water consumers shall have been fully forewarned. And the water company shall immediately notify the Commissioner of Health of such introduction of river water into the water works system.

Harrisburg, Pa., May 4th, 1908.

RIDGWAY, ELK COUNTY.

This application was made by the borough of Ridgway, Elk County, and is for approval of plans for an additional source of supply of water to the public and for the purification of said supply and extension of water works in the town.

It appears that on September fifth, nineteen hundred and seven, the Commissioner of Health issued a permit to the borough of Ridgway, Elk County, Pennsylvania, to extend its water works and to obtain an additional source of supply from Big Mill Creek, under certain conditions and stipulations, among which were the following:

"First. That the intake dam shall be located where it may be advantageously and economically enlarged to a storage dam and equipped to meet future borough demands; and a topographical plan of the basin thus to be formed, and details of the present intake dam, together with the pumping station, well, piping valves and engine layout, shall be prepared and submitted to the Commissioner of Health for approval before construction of this work be undertaken.

"Second. Detail plans of the new storage reservoir on the hill and of the filter plant shall be submitted to the Commissioner of Health, and these structures shall not be built until the plans thereof have been approved by the Commissioner of Health. Particular attention must be paid to the design of the filter plant. It must be operated whenever the pumps are operated and obtain a high degree of efficiency. The borough should employ some qualified expert to select the best point for the erection of the filter plant and to design the details. This will prove true economy."

On October fifteenth, nineteen hundred and seven the borough closed negotiations with a filter company for the erection of a water purifying plant and submitted plans, the details of which were subsequently changed. On October twenty-fourth plans for the dam were submitted and these were subsequently changed. On December seventh, nineteen hundred and seven, plans of the force main and the final filter layout were submitted and on May twenty-eight, nineteen hundred and eight, a formal application for approval of these plans was handed in.

Reference may be had to the permit of September fifth, Nineteen hundred and seven, for a full description of local conditions and the existing water works of the borough.

Big Mill Creek is a mountain stream rising in Jones Township and flowing directly south, a distance of about fourteen miles to the Clarion River, which it enters about two miles below Ridgway. The watershed lies to the west of the borough and it is narrow and long and deep with percipitous sides. The bed of the stream is stony and rather porous and the territory is unoccupied except by a lumbering camp and two farm houses.

In approving this source the Commissioner of Health required that a patrol should be established, that proper sanitary facilities should be maintained at camps and lumber operations, and further, as follows:

"The borough shall immediately disconnect the distributing system with the existing wells at the pumping station and at the Eagle Valley works and at the Dynamo Company's works, and anywhere else, if there be any such connections, and thereafter, upon the introduction of the new supply into town, this and the Gallagher Run supply shall be the only sources used in the public system, and the latter shall be discontinued as soon as practicable."

Gallagher Run rises in the hills southeast of the borough and flows down a steep channel through the borough. Its watershed above the intake dam (a small dilapidated affair) is a little over one mile in area, occupied by two farm houses and yields water enough in wet weather for the town's purposes, but the run goes dry in summer. On the hill is a concrete storage reservoir, circular in form, seventy feet in diameter, twelve feet deep to flow line and is elevated about two hundred and fifty feet above the lower land in the village near the river. This structure was built in nineteen hundred and two at the time the pumping station and drilled

well supply was introduced. The typhoid fever epidemic of nineteen hundred and seven brought about the adoption of the new source and now the borough is prepared to abandon all old sources of supply.

The site of the proposed intake dam and pump house is opposite Ridgway and distant about two miles therefrom. The area of the watershed near where the pipe line of the Ridgway Light and Heat Company crosses the creek and near where the dam is to be erected is thirty square miles and the flow therefrom is about one and a half million gallons per twenty-four hours.

Two hundred feet up stream from the gas pipe line is being erected a substantial masonry spillway dam eight feet high and seventy-six feet along between wing walls and the creek banks, beyond which on either side is being constructed earth embankments with core wall. The dykes being carried up five feet above the crest of the spillway. It is the intention at this time to confine the pool within the banks of the creek. Said banks are ten feet high. The slope of the creek bed is about fourteen feet per mile, so that the dam will back water over half a mile and the pool will be confined wholly within the channel. In the future, if large storage should be wanted, no better site for a dam in the valley is afforded than at the point where the present structure is located. A dam fifty feet high would be about four hundred feet long from hill to hill. Because the structure now planned is not for storage but for intake purposes only, the petitioner asks to be relieved from preparing and filing plans for a reservoir on the creek. This is to be done later should storage ever be required.

On the east end and built into the dam at the wing wall is an intake chamber about five feet square, having a port three by four feet provided with a screen. Instead of a valve there is a stop plank arrangement in front of the screens in the chamber. A sixteen inch cast iron pipe extends from said chamber along the east bank of the creek down stream for a distance of about two hundred feet to the pump house.

Through the bottom of the dam just outside of the intake chamber is a drainage outlet three feet square. It is provided with a plank sluice gate.

The pump house is a concrete building seventy-five feet long and thirty feet wide and its floor is two feet higher than the crest of the dam. Here have been set up the two old pumping engines, gas driven direct connected, each three hundred and seventy-five thousand gallons capacity per twenty-four hours. There is also room for two other engines, one of which is now being installed. It is a Rumsey horizontal tri-plex pump, belt driven, having a capacity of eight hundred and twenty-five gallons per minute against a head of one hundred and fifty pounds. The engine house is a projection thirty by thirty-eight feet of concrete construction, affording accommodations for two gas engines, one only being provided at the present time. Its rated capacity is one hundred and twenty-five horse power. The gas is to be obtained from the adjacent pipe line above mentioned. The power is to be transmitted by belt to shafting in the pump house.

The sixteen inch supply main is connected up to the three pumping engines above described. There will always be at least two feet head of water in it at the pumps. However, it slopes towards the intake chamber and may be drained into the same whenever the chamber is emptied. A large drain opening is provided at the bottom of the intake for this purpose.

The force main is twelve inches in diameter. It has been laid over the hill to the town in a right of way purchased in fee by the borough. The summit is two hundred and twenty-nine feet above the pump house floor and two hundred and seventy-five feet above Main Street in the town. Air valves and blow-offs are provided at proper points along the line. The site for the distributing reservoir on the hill base been selected but not purchased because the borough is without sufficient funds. Later, details of a distributing reservoir will be prepared and submitted for approval as ordered by the Commissioner of Health. Mill Creek water is to be furnished to the town direct. The surplus pumpage will overflow into the present Gallagher Run distributing reservoir.

The plans for the water purification plant call for feed and wash pumps, chemical and subsidence tanks, mechanical feed and wash pumps, chemical sand filters, filtered water basin with accessories capable of adequately purifying Mill Creek water at the rate of one million gallons per twenty-four hours. Outside and in the corner adjacent to the pump and engine house has been built into the ground below the foundation of said pump and engine house are re-inforced concrete water tight structures fifty-eight feet long and twenty-one feet wide interior dimensions, carried up eight feet above the surface of the ground and backed by earth slopes on two sides and one end. In the corner abutting the pump and engine house the concrete walls support a superstructure whose roof is contiguous with that of the adjacent buildings. Elsewhere the walls support a flat concrete roof, level with top of earth embankments.

The inner half of the structure next to the buildings comprise the filtered water basin. The outer half is designed for subsidence purposes.

The centrifugal feed pump and the centrifugal wash water pump are located in the pump house in the corner near the filter plant. The former has a capacity of one million gallons daily and the latter two thousand gallons per minute. Both are so arranged as to be available for feeding raw water to the subsidence tank or washing the filters either with filtered water or with raw water.

The coagulent feed apparatus is to consist of two solution tanks, each four feet in diameter and four feet high. Two variable stroke coagulent solution pumps to be actuated by the high service pump so that each revolution will cause a stroke or displacement of the coagulent feed pump are to be provided. The application of the coagulent to the raw water is to be into the eight inch feed pipe beyond the centrifugal feed pump between it and the subsidence basin. The amount of solution applied will be in direct proportion to the amount of water being drawn from the filtered water basin. It is intended to use sulphate of alumina as a coagulent. Should the raw or applied water be low in alkalinity, one solution tank and pump may be used for applying lime water or soda solution, while the other solution tank and pump supplies the coagulent.

The sedimentation basin is twenty-eight feet long by twenty-one feet wide and will contain water to a depth of sixteen and one-half feet, giving a storage capacity, deducting partition walls, of sixty-nine thousand gallons, equivalent at the nominal rate of the entire plan to about one and a half hours' sedimentation, which should be ample for Mill Creek water. This stream does not become very turbid and the suspended matter during freshet periods is coarse and easily settled.

The raw water is to be delivered through an eighteen inch pipe into the stilling chamber of the subsidence basin, this chamber being about two and a half feet wide and ten feet long in the clear, the inner wall being perforated with one and three-quarter inch holes, twelve inches on centres, arranged in parallel rows eighteen inches apart. In the bottom of this wall there is provided an equalizing valve The end of the delivery pipe within the stilling chamber is to be provided with a butterfly valve actuated by a proper float, for controlling delivery of water into the basin and to prevent its overflow. An overflow pipe and also drain connection will lead to the main ten inch drain which extends to the creek opposite the station. The drain will receive all waste water from the plant but no sewage. A cement vault with privy superstructure is provided outside of the buildings in the yard. Water will enter the main basin through the perforated stilling wall, travel full length of basin, pass round end of centrally located baffle wall and finally over the weir of skimming wall whence it will be conveyed by a six inch gravity to the filter unit.

There are to be two rectangular concrete gravity filters each eighteen feet long and ten feet wide, built side by side over the filtered water basin below. One-half of their length will be enclosed in the filter house where the sand surface will be open to view. The pipe gallery and operating floor above in front of the filters will be in the filter house, all resting on substantial concrete construction, forming the roof of the filtered water basin.

Across the floor of each filter a heavy cast-iron main collector, made in sections, elliptical inform and having flanged and faced joints is to be laid. This collector will have an area equal to twenty-eight square inches. It will have bosses on either side and the bosses will be tapped six inches apart to receive lateral or strainer pipes, which will be one and a quarter inches in diameter. These small pipes will be tapped six inches centre to centre to receive the level of the strainers and so cover all the pipes with a layer of concrete. There will be about seven hundred strainers in each filter and they will be distributed as nearly as possible on six inch centres. The aggregate strainer area will be less than the cross section of the main collector, so that the washing effect will be uniform and regular. A tested effluent controller will be placed at the outlet of each filter so that the rate of filtration can be controlled between four and six hundred thousand gallons per day, and these controllers will have valves so that the rate can be controlled within two per cent. of any desired amount. Each filter will be provided with good loss of head gauges. The filter piping will consist of settled water inlet pipes, wash water inlet pipes, wash water outlet pipes, filtered water to the filtered water basin pipes, and filtered water to waste pipes. These pipes will vary from six inches to ten inches and will be adequate for the purpose. Equalizing or balance valves will be placed on the stilling wall and weir wall of the coagulating basin, so that the water level in the filters and the subsidence basin will be kept reasonably constant.

Over the strainer system of each filter is to be sprayed an eight inch layer of screened gravel and upon it thirty inches in thickness of selected filtering sand. Each filter unit is to be equipped with a heavy sheet iron wash trough set eighteen inches above the top of the sand to admit of the washing of the filter at a rate of about ten gallons per square foot per minute.

Filtered water basin beneath the filters is to be twenty-eight feet in length and twenty-one feet in width and with a depth of seven feet of water the capacity will be thirty thousand gallons.

Each filter contains one hundred and eighty square feet of effective filtering area and as each is guaranteed to deliver five hundred thousand gallons per twenty-four hours, the rate of filtration will be less than one hundred and twenty-five million gallons per acre per diem. When delivering water at the five hundred gallon rate, if the filter companies guarantee shall be obtained, the water will be bright and clear and when the number of bacteria in the raw or unfiltered water is three thousand or more per cubic centimeter, the bacterial reduction is to be not less than ninety-seven per cent. as determined by an examination of not less than thirty samples collected within a period of not less than fifteen days; and when

the number of water bacteria in the raw water is less than three thousand, the filtered water shall not contain more than an average of one hundred bacteria. This guarantee is subject to the conditions that the filter plant be operated in accordance with the instruction of the filter company.

A sixteen inch suction pipe is inserted into the clear water basin to within eighteen inches of the bottom by means of which the water is to be supplied to the town. The consumption is now about five hundred thousand gallons daily, so there is over an hour's storage in the filtered water basin.

The emergency intakes at the industrial works now connected with the town pipe system have been placed under seal, the type of seal being that in ordinary use on freight cars.

The purification works as herein described and the entire layout is of good design, economically arranged and should afford to Ridgway borough a valuable asset. The dam and different parts of the works have been under construction for several months and it is expected that filtered water may be delivered to the town within a few weeks. Details of the original plans have been altered to increase the efficiency and the economy of the plant, all of which reflect credit upon the prudence and ability of the local authorities.

It has been determined that the interests of the public health will be subserved by approving the plans and issuing a permit therefor and a permit is hereby and herein granted under the following conditions and stipulations:

FIRST: That a plan of the water pipe system in the borough showing the sizes and location of pipes, location of gates, blow-offs and drainage facilities shall be prepared forthwith and filed in the office of the Commissioner of Health. And thereafter, at the close of each season's work a plan of the water pipes laid during the year shall be prepared and filed in the office of the State Department of Health, together with any other information in connection therewith that the Commissioner of Health may require.

SECOND: Weekly reports of the operation of the water works system, particularly the purification plant, shall be kept on blank forms satisfactory to the State Department of Health, copies thereof shall be filed in said Department. The borough shall assist the Commissioner of Health in making such tests of the plant from time to time as may be found desirable. If necessary, the Commissoner of Health may prescribe standards of efficiency and make regulations for the operation and maintenance of the plant. If at any time, in his opinion, the water works system, or any part thereof, or the water furnished thereby has become defective or insufficient or prejudicial to the public health, then such remedial measures shall be adopted by the borough as the Commissioner of Health may advise or approve.

THIRD. The borough shall filter all of the water supplied to the town. Only in some great emergency shall raw creek or river water be introduced into the system At such time the public shall be amply warned to boil the water and as soon as practicable the water pipe system shall be drained and thoroughly flushed.

Harrisburg, Pa., June 18, 1908.

RIVERTON, CUMBERLAND COUNTY.

This application was made by the Riverton Consolidated Water Company of Riverton Village, Lower Allen Township, Cumberland County, Pennsylvania, and is for permission to obtain a temporary supply of filtered water from the city of Harrisburg.

It appears that in pursuance of the terms of a permit and decree bearing date of August eighteenth, nineteen hundred and eight, and issued to said water company by the Commissioner of Health, the water company is now engaged in the preparation of plans for the construction of its own water purification plant, which plans will be submitted to the Commissioner of Health for approval. The works, however, cannot be constructed and put in operation at an earlier date than the summer of nineteen hundred and nine. Meantime, the public must continue to be furnished with the Susquehanna River water, the safeguard to public health in such use being the boiling of the water. As evidence of good faith and to meet the public demand in its charter territory the Riverton Consolidated Water Company now seeks to supply the people with filtered water at once.

The city councils of Harrisburg have enacted an ordinance which has been approved by the Mayor, providing for the sale within the city limits to the Riverton Consolidated Water Company of filtered water, the water so purchased to be used for a public supply in the chartered territory of the water company for an indefinite term but with the understanding that the expiration of the term will be at the date when the water company shall have installed its own water purification plant in pursuance of the said decree of the Commissioner of Health of August eighteenth, nineteen hundred and eight.

A permit is hereby and herein granted to the Riverton Consolidated Water Company to obtain its source of supply from the city of Harrisburg as proposed, pending the carrying out of the stipulation in the decree of August eighteenth, nineteen hundred and eight.

Harrisburg, Pa., October 15th, 1908.

ROULETTE, ROULETTE TOWNSHIP, POTTER COUNTY.

Roulette Water Company.

This application was made by the Roulette Water Company, Roulette, Roulette Township, Potter County, and is for permission to obtain an additional source of supply.

It appears that the village of Roulette, a manufacturing and farming community of about eight hundred inhabitants, is situated in Roulette Township, in the western part of Potter County and along the Allegheny River ten miles below and west of Coudersport, the county seat of Potter County. The Coudersport and Port Allegheny Railroad passes through Roulette to its junction with the Buffalo Division of the Pennsylvania Railroad at Port Allegheny, seven miles west of Roulette.

The inhabitants of Roulette are dependent for employment upon a small chemical works and stave factory and to a certain extent to farming and lumbering in the vicinity. The latter industry is becoming rapidly less important as a large part of the timber in the locality is exhausted. Although the village is in the gas fields, this industry furnishes employment to but few of the inhabitants. A glass works, at one time the mainstay of the community, was burned down during the current year and it has not resumed and, it is reported, will not resume operations. As a result the population of the town has been diminished from twelve hundred in nineteen hundred and seven to eight hundred.

The Allegheny River pursues a westerly course through the village and divides it into a north and south section. The principal or business section is to the north.

Fishing Creek has its source in the mountains, six miles northeast of Roulette, and follows a southwesterly course to its junction with the Allegheny River in the western end of the village.

Lanegar or Lanning Creek, a small mountain stream, has its source about three miles south of Roulette and flows northerly to its junction with the river in the eastern end of the village.

A public sewerage system does not exist in Roulette. Three residences and one hotel are accommodated by three private sewers, two in the southern section of the town and one in the northern section. These sewers discharge into the river. There are fifteen cesspools and two hundred and twenty-one earth privy vaults in the village.

The Roulette Water Company supplies one factory and one hundred and three of the two hundred and forty houses in the town, the remaining inhabitants obtain their supply of water from dug wells and a few drilled wells and springs.

The Roulette Water Company was chartered February third, nineteen hundred and four, for the purpose of supplying water to the public in the township of Roulette, Potter County.

In nineteen hundred and four, the water company laid about two miles of two inch and three inch cast-iron and wrought iron distributing pipes in the village and about a mile of four inch cast-iron gravity main, extending southward from the town in and near Lanegar Creek Road to a point where the pipe line branches, a short branch extending to each of the two reservoirs. These reservoirs were constructed by the water in nineteen hundred and four and are located in Roulette Township about five hundred feet from Lanegar Creek, one on the western and one on the eastern slope.

Reservoir Number One on the western slope was excavated in the side hill and has a masonry breast forty-five feet long on the one side. A spring in the bank at the upper side of the reservoir is its only source of supply. On October eighth, nineteen hundred and eight, this spring was dried up and the reservoir was empty, due to the general drought and to the drilling of numerous gas wells on the summit, one-quarter of a mile to the west. A gutter was dug around the upper side of the reservoir to keep out surface drainage. The reservoir has a capacity of twenty thousand gallons and at elevation of about one hundred and ten feet above the village and when it is full the water has a surface area of one thousand square feet and a depth of five feet at the breast. There is a valve on the supply pipe at the reservoir so that the water may be shut off and there is a separate pipe by means of which the reservoir may be drained. There is no fence around the reservoir and it is not otherwise protected and is only about fifty feet from the public road.

Reservoir Number Two on the eastern slope immediately opposite Reservoir Number One was excavated in the hillside and has a masonry front and ends. It is fed by a small spring in the bank at its upper side. This reservoir has a capacity of two hundred thousand gallons and an elevation of about one hundred and ten feet above the village and when it is full the water has a surface area of four thousand feet and an average depth of seven feet. There is a shut-off valve in the supply main at the reservoir and there is a separate pipe by means of which the basin may be drained. The reservoir is entirely enclosed by a wire fence and a ditch has been dug around its upper side to keep out surface drainage. The slope above this basin is uninhabited second growth timber land.

A well was drilled and a pump installed in the eastern end of Roulette, north of the Allegheny River about one hundred and fifty feet from the water's edge and immediately west of the highway bridge across the stream and water from the well

was pumped into the distributing system at this point. This was one of the principal sources of supply from the beginning of the operation of the water works, but the arrangement was found unsatisfactory and was abandoned in nineteen hundred and seven, and the pumping machinery has been removed.

In nineteen hundred and seven the water company, having abandoned the well, and without having made application to the Department of Health, constructed an intake dam on Lonegar Creek at a point directly between the two reservoirs. A wooden breast about twenty feet long forms a basin with a capacity of five thousand gallons. A three inch cast-iron pipe, in which there is a shut-off valve, leads from the dam to the gravity main from the two springs. The dam is at an elevation little lower than the springs, about one hundred feet above the village.

The watershed of Lonegar Creek above the intake has an area of two and a half square miles, and is for the most part heavily wooded with second-growth timber; but contains some farmland. Immediately above the dam and along the public road are a school house and four dwellings and the accompanying outbuildings, all built close to the creek, which receives surface drainage from the barn yards, pig pens, privies and dwellings. There are approximately thirty persons living in the watershed, exclusive of the school children, a large number of whom come from the village of Roulette.

The one hundred and three houses supplied by the water company are scattered throughout the village, which covers about one square mile. There are numerous dead ends throughout the distributing system, but it is reported that all these and also all low points are provided with blow-offs. The consumers number about six hundred and the average consumption is reported to be thirty thousand gallons per day. Of this amount one thousand gallons are used for manufacturing purposes. The chemical works in the southeastern corner of the village has a private drilled well and pump.

The application of the water company states:

"That the Roulette Water Company is not intending to extend its service nor to use additional source of supply, but merely to take water from the stream now in use at a point higher in its course. As your Department has already been informed, the springs which have furnished the Company's supply have been so impaired by the drilling of gas wells in the vicinity that in dry times their flow is not sufficient. The Company has operated a pumping plant drawing water from a deep well. Whenever this pump is out of order it has been necessary to use water from Lanegar Creek. Complaint has been made to your Department in this regard. To place its plant above any criticism the company desires to lay four hundred and twenty rods of line up Lanegar Creek to a point above all buildings where the stream comes from the forest and to take water from that point. And further sets forth there is no source of pollution above the point where the Company proposed to take water."

The Water Company purposes to construct an intake dam across Lanegar Creek in Roulette Township at a point about two and three-quarter miles south of the village, and about one and one-quarter miles above the present intake and above all habitations; the nearest dwelling is one thousand feet below. The principal sources of Lanegar Creek are three springs about three-quarters of a mile above the site of the proposed dam. The drainage area above this site is uninhabited and entirely covered with second growth timber and contains about one square mile of Roulette and Keating townships.

The depth of water at the masonry breast is to be about four feet six inches and a six inch drain pipe is to be provided in the bottom of the dam. This proposed intake site is about one hundred feet higher than Reservoir Number One. A three inch pipe draining from above the bottom of the dam is to carry water from the proposed intake to Reservoir Number One, whence the supply will be furnished through the existing pipe system.

Lanegar Creek is now the principal source of supply for Roulette and it is a dangerous source at the point of the existing intake. The spring in the bank of reservoir Number Two furnishes perhaps five per cent. of the town's consumption and the spring in the bank of Reservoir Number One at times dries up completely. Therefore the abandoning of the present intake in Lanegar Creek and the obtaining of an unpolluted source of supply is desirable in the interests of public health.

Apparently Lanegar Creek at the site of the proposed intake would furnish a satisfactory and uncontaminated supply of water sufficient in quantity to meet the demands of the consumption upon the system. The flow of the stream at this point on October eighth, nineteen hundred and eight, was estimated at seventy-five thousand gallons per day. Proper precautions should be taken to protect the proposed sources from chance contamination and the watershed should be occasionally patroled with the same object in view.

It would be well to arrange the piping so that the water from the proposed source may be allowed to flow into either of the existing reservoirs at the springs without interrupting the continuous flow of water to the village in order to make it possible to keep a supply in storage in case it should be desirable to temporarily discontinue furnishing water from any one of the sources. It would thus also be possible to provide several days of settling for the supply, if desirable. The present intake in Lanegar Creek should be abandoned and the piping connection removed. Reservoir Number One should be efficiently fenced to prevent chance or malicious pollution.

Conditions are such that an outbreak of typhoid fever in Roulette among the users of the public water supply might occur at any time.

It has been determined that the proposed additional supply will not be prejudicial to the public health under certain conditions, and a permit is hereby and herein issued therefor, under the following conditions and stipulations:

FIRST: The water company shall immediately and so long as water is furnished from the present intake in Lanegar Creek, notify and continue to notify its consumers by means of placards posted in conspicuous places, of the danger of using the public water supply for drinking and culinary purposes without the water being previously boiled.

SECOND: On or before April first, nineteen hundred and nine, the water company shall prepare and file in the office of the State Department of Health a plan of its distributing system, showing valves, blow-offs and sizes of pipe and plan and profile of the supply main of the town, showing all valves, blow-offs and connections and detail plans of the two reservoirs, showing all connections and drainage facilities. At the end of each season's work a plan shall be prepared and filed in the office of the State Department of Health showing the additions made to the distributing system of pipes in the streets during the year and such other information as may be required, in order that the Department may always be fully informed of the extent of the water works system and the public use thereof.

THIRD: If necessary to keep cattle away from the banks of the intake reservoir, a fence shall be constructed around it and ditches shall be built, if necessary, to prevent surface drainage from adjacent farm and pasture lands entering the reservoir, and adequate facilities shall be provided by means of which the proposed reservoir may be flushed out and cleaned, and adequate drainage facilities shall be provided at low points on the proposed pipe line, and a valve shall be provided in the supply pipe at the reservoir, so that the supply may be shut off from the town if desirable.

FOURTH: Before the proposed works are built, detail plans of the dam and of the reservoir to be formed above it and a plan and profile of the location of the supply pipe and plans showing the connection of the supply pipe to the existing system shall be submitted to the Commissioner of Health for approval. Before the proposed source of supply is used by the water company, a plan of the watershed above the proposed intake, showing wagon roads and streams and any possible source of pollution, shall be prepared and filed by the company in the office of the State Department of Health.

FIFTH: The water company shall maintain a monthly sanitary patrol of the watershed and reports thereof shall be filed with the State Department of Health. Should a lumber camp or any habitation be established on the watershed, the water company shall see that proper receptacles for sewage are provided at all such occupied camps or estates and that these receptacles shall be used and properly maintained to prevent any contamination whatsoever of surface waters on the watershed. Any neglect on the part of any owner or individual to comply with sanitary regulations shall be promptly reported by the water company to the Commissioner of Health.

SIXTH. The company shall keep monthly reports of the operation of its system on blank forms satisfactory to the Commissioner of Health and submit copies thereof for filing with the State Department of Health whenever this is required.

SEVENTH: If at any time in the opinion of the Commissioner of Health, the water supply or water works, or any part thereof, is found prejudicial to the public health, then the water company shall adopt such remedial measures as the Commissioner of Health may advise or approve.

EIGHTH: When the proposed extension has been made and water is being supplied thereby, the pipe connection from the present intake in Lanegar Creek to the supply main shall be taken out and thereafter no water shall be supplied to the public taken from Lanegar Creek below the site of the intake for which a permit is herein granted.

NINTH: On or before January first, nineteen hundred and nine, a substantial fence shall be constructed around the reservoir Number One to effectually prevent chance or malicious contamination of its waters.

Harrisburg, Pa., November 23rd, 1908.

ST. MARYS, ELK COUNTY.

St. Marys Water Company.

This application was made by the St. Marys Water Company of the borough of St. Marys, Elk County, and is for permission to secure an additional source of supply.

St. Marys is a manufacturing community of about sixty-four hundred population, located on Elk Creek in Benzinger Township, Elk County. Elk Creek is a tributary of the Clarion River which empties into the Allegheny River. The creek has its head waters in the hills in the township surrounding the borough, these hills being the summit of that part of the Allegheny Mountains which form the divide between the Susquehanna River and the Ohio River basins.

The town is located in the creek valley and it extends up on the hillside where many of the dwellings are located.

The St. Marys Water Company was chartered in eighteen hundred and eighty-nine and works were built in that year and the year following and the public in the borough has since been supplied with water for domestic and fire protection purposes. A number of the manufactories use the water.

There are two sources of supply besides the additional source which has been introduced and for which approval is asked.

One of the two supplies is Silver Creek. This stream rises in the township north of the borough and flows southerly, joining Elks Creek a short distance below and west of the borough.

The other source is obtained from Laurel Run. This stream rises in the hills five miles south of the borough in Fox Township, and flows northerly, emptying into Elk Creek a mile or more down stream below the mouth of Silver Creek.

The Silver Creek supply is drawn from an intake dam made of timber and earth and pumped through a six inch rising main to reservoirs elevated one hundred and thirty-five feet above the pumping station and one hundred and eighty-four feet above the borough in the valley. The dam is about ten feet high and stores approximately four million gallons. The watershed above this reservoir comprises about one hundred acres. There is one dwelling on this watershed and it is in the vicinity of the living springs which form the head waters of Silver Creek. On a little tributary brook has been erected a small dam and reservoir which is utilized to store some spring water and discharge it through an eight inch pipe into the reservoir at the pump house. There are three drilled wells at the pump house, each three hundred and fifty-five feet deep, being cased off with eight inch and six inch pipe to the rock which lies eighty feet below the surface. Water flows from these wells into a well at the pump house. The pumping machinery comprises two pumps each half a million gallons capacity per twenty-four hours, one being operated by a gas engine and the other by a steam engine.

The distributing reservoirs are located in the extreme northwestern corner of the borough on the hill and adjacent to St. Michael Street. They are both of the same size, thirty feet wide by eight feet long and eight feet deep, being practically excavations in the ground whose sides are held in place by two inch plank and timber work. Over all is an A roof, designed to afford protection from pollution. A six inch distributing main leads from the reservoirs down St. Michael Street to the town.

The water from the wells at the pump house is abundant, clear, colorless and appears to be of good quality.

The water from the various springs is also of excellent quality where it gushes forth from the ground, but the conditions existing on the Kerner farm, whereon the springs are located, are unsanitary. The two large springs back of his dwelling flow into a duck pond. Kitchen slops and wastes are thrown out from the house onto the ground within a few feet of the largest spring immediately back of the house. A hen house is immediately over another small spring. A pig pen and yard crosses the stream below the duck pond. The house privy vaults on the slope one hundred feet away, where surface drainage can reach the run. The large manure pile at the barn stands in a pool when it rains or it would do so if there were not a drain under the road which carries the water away to the run. These unsanitary conditions are represented by the water company to be the result of wilful intention of the owner of the property in order to compel the water company to purchase the farm at an exorbitant price. It is reported that the water company has offered to put the premises in a sanitary condition and maintain them, but that the owner has refused to enter into any negotiations with the company for the abatement of the menaces.

The source of the Laurel Run supply is an intake dam built of concrete which impounds about five million gallons and has a contributing area of three hundred and seventy-five acres, owned almost entirely by the water company. There are numerous springs of clear, cool and sparkling water which gush forth from the mountain side and furnish a never failing flow into the reservoir. The watershed is principally wooded and is reported to be uninhabited. The sides and bottom of the flooded area of the dam were stripped of all organic matter. A suction pipe leads from the reservoir to the pump house. There are two eight inch pipes, one leading to each pump. The pumping engines are driven by a gas engine and each is capable of raising from five hundred thousand to eight hundred thousand gallons in twenty-four hours. At the pump house there are three driven wells, having a depth of about three hundred feet and cased off to rock in the usual manner. They do not flow. Water has to be raised from them by the pumping engines.

There is a six inch rising main through which the Laurel Run water is forced to a reservoir known as Laurel Run Reservoir and located on the hill in the township immediately south of the borough. This structure is the same construction and size and has the same elevation above the borough as the two distributing reservoirs above described and located on St. Michael Street. A six inch gravity main delivers the water into the town.

During dry weather the above sources of supply are insufficient to supply enough water for all the demands. The maximum daily consumption is one and a half million gallons and it would be more if the company could supply the water.

The tanneries in the town use considerable water and so do the other industrial plants. Certain outlying districts in the town have not yet been furnished with public water and in these districts the springs and ground water now used by the people for drinking purposes are very liable any moment to become polluted by surface drainage. The borough is now undertaking the construction of a public sewer system to do away with these conditions, but even then the use of domestic well water anywhere in town is bound to be accompanied by danger to a greater or less degree. An active demand for extension of the street water pipes resulted in the water companies making additions to the source.

Wolf Lick Run rises in the mountains on the south side of the ridge from whose north slope flow the springs which are the headwaters of Laurel Run. The course of Wolf Lick Run is southeasterly into Spring Run which empties into the Sinnemahoning Creek, one of the main feeders of the West Branch of the Susquehanna River. On this run at a point above which the drainage area is twenty-five hundred acres, all of which are owned by the company with the exception of a forty-three acre tract on which resides the only inhabitant of the watershed, the company has constructed a new storage reservoir with a capacity of about ten million gallons. The dam is a substantial concrete structure about two hundred feet long and twenty feet high. All organic matter was stripped from the area flooded by this dam. A pump house and gas driven pumping engine of a million gallons capacity daily have been erected and water during the summer of nineteen hundred and seven was pumped through an eight inch force main to a new distributing reservoir of the same size and construction and elevation as the other distributing reservoir hereinbefore described. The Wolf Lick reservoir is on the hill immediately south of the borough in the general neighborhood of the Laurel Run distributing reservoir. A six inch connecting pipe has been laid between the two supplies at the reservoir.

At the farm house on the watershed which is near the source of one of the tributaries there is a duck pond immediately below the house and one side of the pond is a pig pen and yard. The barn yard and manure pile are nearby, the ground sloping quite rapidly from them towards the stream and pond, so that whenever it rains the wash is directly to the run. A spring gushes out a short distance to one side of the house and flows into the run below the duck pond. Immediately over the banks of the brook is a privy. The water company has failed in its attempt to negotiate with the owner of the property for the purchase of the land or for the abatement of the menaces.

The water company has a contract with the borough to supply all its inhabitants at all seasons of the year with an abundance of water. The additional source of supply is thought to be equivalent to eight hundred thousand gallons per day. The company asks approval of this and the original supplies and for permission to make extensions to the water works system in the town.

It is clearly apparent that the waters from the three mountainous watersheds, supplied as they are by springs and coming from practically uninhabited areas, should furnish to the inhabitants of St. Marys borough as desirable a quality of water as it is possible to obtain, provided the menaces at the two dwellings above mentioned be removed, and conditions be established and maintained whereby danger from these sources shall be eliminated. The State Department of Health can cause an abatement of the menaces and the water company can maintain a patrol and make sanitary inspections at frequent intervals and keep the Commissioner of Health informed of any improper disposition of sewage at the occupied property or of the existence of any unsanitary conditions. The law of nineteen hundred and five to preserve the purity of the waters of the State for the protection of the public health has for its object the prevention of just such pollutions as now exist on the Silver Creek and Wolf Lick Run watersheds.

The water company has failed to submit sufficient detail plans of its dams, pumping stations, force mains, reservoirs and distributing pipes to enable the State Department of Health to become thoroughly informed of the system and to direct the supply of water to the public in the case of the outbreak of an epidemic in the town. Such plans should be submitted.

It has been determined that the proposed additional source of supply will not be prejudicial to the interests of the public health and the same is hereby and herein approved and a permit granted therefor and for the extension of water pipes in the borough of St. Marys, under the following conditions and stipulations:

FIRST: That detail plans of all dams, reservoirs, pumping plants, force mains, distributing reservoir and pipes shall be prepared and filed in the office of the State Department of Health, together with accurate plans of the watersheds of the supplies. At the close of each season's work a plan of all extensions made to the street pipe system during the year shall be prepared and filed in said office, together with any other information in connection therewith that may be required, to the end that the Commissioner of Health may be always informed of the extent of the water works system and the number of people supplied with such water.

SECOND: Adequate facilities for the quick drainage of every part of the water works system shall be afforded, and these drainage points shall be adequately designated on the plans to be filed with the State Department of Health.

THIRD: The water company shall maintain adequate patrol of the watersheds to see that proper receptacles are provided and used and maintained on all occupied estates and that all reasonable precautions be taken to prevent any contamina- whatsoever of the waters to be supplied to the public. Monthly reports of all inspections shall be sent to the Commissioner of Health.

FOURTH: If at any time, in the opinion of the Commissioner of Health, the water supply or the water works, or any part thereof, has become prejudicial to the public health, then the water company shall adopt such remedial measures as the Commissioner of Health may approve or suggest. In this connection the Commissioner will cause a sanitary inspection of the occupied properties on the watershed and will forthwith issue orders for abatement of menaces. In this work and subsequent proceedings the water company shall assist the State Department of Health.

FIFTH: The Company shall keep a weekly report of the operations of the works on forms satisfactory to the Department of Health and submit copies thereof to the Commissioner of Health when required.

Harrisburg, Pa., May 4th, 1908.

SHEFFIELD TOWNSHIP, WARREN COUNTY.

Sheffield Water Company.

This application was made by the Sheffield Water Company, of Sheffield Township, Warren County, and is for permission to extend its water works for the supplying of water to the public in the village of Sheffield, said township.

In eighteen hundred and eighty-seven, a partnership by the name of Horton, Crary and Company, locally known as Deer Lick Water Company, constructed a small dam, impounding about one and a half million gallons of water on Deer Lick Run in Sheffield Township and piped the water to the village of Sheffield, situated at the confluence of Two Mile Run and Tionesta Creek, principally to supply water to the tanneries located there. Subsequently the tanneries passed to the Penn Tannery Company and finally to the Elk Tanning Company, but the water works system was retained by the original owners.

At joint expense the water company and the Penn Tanning Company from time to time made some improvements and operated and maintained the plant and to increase the supply drilled a well at the Sheffield Tannery and installed a pump there and made connections with the street pipe lines.

Some time after May first, nineteen hundred and five, on which date the Elk Tanning Company acquired the Penn Tanning Company's properties, it became apparent that the water works system had been reserved. The Sheffield Water Company, still an association unincorporated, made demands for water rates of the Elk Tanning Company. The latter concern refused to pay them rates on the ground that the water works plant was a joint property. The question was litigated, the trial court decided in favor of the water company and an appeal to the Supreme Court is now pending.

Meantime, in the fall of nineteen hundred and seven, the Elk Tanning Company, having made other provisions for water, entirely abandoned the use of the water company's supply, with the exception, however, of the well and pumps on the Elk Tanning Company's property at the Sheffield Tannery.

The village is an important lumbering centre for the district. It is located in a mountainous well timbered region in the southeastern corner of Warren County on the main line of the Pittsburgh and Erie Railroad, about thirteen miles east of Warren.

The railroad comes down the valley of Two Mile Run from the east and passes up the valley of Tionesta Creek westerly. At the forks of the streams is the Sheffield Tannery, a half mile up Two Mile Run is the Tionesta Tannery and about five hundred feet northwest of the confluence of the banks of the main stream is the Horton Tannery. Three-quarters of mile above this point is the Sheffield Saw Mill of the Central Pennsylvania Lumber Company, a corporation allied with the interests of the Elk Tanning Company, which latter concern owns and operates the tanneries. The saw mill is a new plant and will give employment to a large number of men. In between the works above mentioned the territory is well built up and comprises the village. The population is said to have doubled since nineteen hundred and at present is about two thousand. Conditions are prosperous and a moderate growth may be anticipated. The terminal of the Sheffield and Tionesta Railroad and the main offices and shops of the narrow gauge road called the Tionesta Valley Railroad are here.

The policy of the Elk Tanning and Lumber Company is to erect dwellings for its employes and to equip the dwellings with running water and modern plumbing facilities. It is reported that during the last year thirty-two such houses were constructed. The tanneries and these houses are now supplied with water taken from various sources, partly from springs on the hillside and from individual wells, and partly from the driven well at the Sheffield Tannery. This well water is salty and not desirable. Some water is taken from Two Mile Run at the Tionesta Tannery and supplied to the works and the houses in the vicinity belonging to the

Elk Tanning Company. It is in this manner that the said tanning company at present obtains the water used by it for manufacturing and domestic purposes. A plan has been prepared for a new water works system to adequately furnish a pure mountain water to the tanneries and the properties of the Elk Tanning Company and its allied interests. An application for a charter has been filed in the office of the Secretary of State and approval of the plan by the Commissioner of Health has been requested by the incorporators under the name of the Citizens Water Company of Sheffield.

On April seventeenth, nineteen hundred and six, the Sheffield Water Company was duly chartered under the laws of the State for the supply of water to the public at the village of Sheffield, Warren County.

The intake dam at Deer Lick Run is distant from the village about one and a half miles. Since the incorporation, the water company has rebuilt the dam, raised the surface of the water about five feet and removed all vegetable matter and soft mud from the bottom of the reservoir, excepting a small portion of the upper end thereof. As it now exists there is a log dam about fifteen feet high impounding about four and one-half million gallons of water area between one and five-tenths and two acres in extent, the elevation being sufficient to maintain a pressure of about seventy pounds in the village. Details of this structure and of the reservoir have not been filed in the Department's office. It is understood, however, that the supply main is eight inches in diameter and that on its line to the town there are opportunities for blow-off and drainage.

The area contributing to this reservoir is reported to be two and a half square miles of mountainous, well timbered land. The Central Pennsylvania Lumber Company owns most of this territory and lumbering operations of more or less extent may occur there. At the present time there is a small camp on the area and hardwood is being removed.

The population in the village now using the public supply is said to approximate sixty-five per cent. of the entire community. Demands for extension of the water works pipes made from time to time in the past by residents of the Northwestern section were denied on the ground of an insufficient supply. This was before the enlargement of the storage capacity of the reservoir and the discontinuance of the supply to the tanneries. During nineteen hundred and seven, or since the incorporation in nineteen hundred and six, extensions of street mains were made at various points in the town and it is understood that at the present time there are about four miles of street pipes whose diameters range from three to eight inches. The system seems to be well designed and the pressure under ordinary circumstances good. Dead ends are few and usually a fire hydrant is placed at such ends. There are about forty fire hydrants. The company is not under contract to maintain the hydrants. The insufficiency of the pressure and the supply during fires was one reason for the making of connections to the streams for use in an emergency at two of the tanneries. These connections, however, had been cut off prior to the stopping at the tanneries of the use of the water company's supply.

The petitioners purpose to make improvements from time to time in the village as necessity may require and to increase the source of supply, if need be, by adding to the storage in the reservoir and by intercepting the flow from certain copious springs there whose discharge is now into the run below the dam. Details of these extensions and additions have not been submitted because the improvements are not contemplated for the present.

The extensions made by the petitioners since Act one hundred and eighty-two of nineteen hundred and five became a law were made not with the intention of defying the provision of the law; but as soon as the water company became aware of the necessity of filing plans of existing water works and of receiving approval for extensions thereof, it prepared and submitted the plans and applications now before the Department.

It is represented that the shortage of water during the summer of nineteen hundred and seven was prior to the discontinuance by the tanneries of the use of the Sheffield Water Company's supply, and that had the tanneries not made a wasteful use of the supply there would have been an ample quantity of water on hand in the reservoir during the drought to have furnished the entire village with water without deficiency. The petitioners further represent that for some time in the future the system of water works as now operated will be ample for the supply of water for domestic uses in the village.

It was during the drought of nineteen hundred and seven that citizens of Sheffield made a formal protest to the Commissioner of Health relative to the shortage of water and asked that the water company be ordered to have recourse to the driven well supply as a temporary expedient. The Department has not determined the question of proprietorship in this well and the matter seems immaterial because the petitioners do not ask approval of this source of supply nor do they contemplate the use of it.

The danger of contamination of Deer Lick Run waters lies in possible pollution at camps or from lumbering operations. It should not be a difficult matter for the company to patrol the watershed sufficiently to keep informed of the sanitary condition at all buildings, camps and operations and to enable it in conjunction with the State Department of Health to enforce sanitary regulations to preserve the purity of the waters.

Provided the quality of the reservoir water should deteriorate because of lack of adequate removal of mud, soil and vegetable matter or other deleterious substances from the site of the reservoir, a remedy should be easily at hand.

In view of the above circumstances, it has been determined that the proposed extensions will not be prejudicial to the public health, and approval is hereby and herein given to the improvements made to the water works system subsequent to April twenty-second, nineteen hundred and five, all under the following conditions and stipulations:

FIRST: That the water company shall prepare a plan of its existing water works system in the village showing thereon the location of hydrants, gates, blow-offs and the sizes of the pipes The company shall also submit a similar plan and profile of the supply main to town, together with plans and elevations of the dam and reservoir. At the close of each season's work, a plan of the water pipes laid during the year shall be prepared and filed in the office of the Commissioner of Health, together with any other information in connection therewith which may be required.

SECOND: Before any additional source or extensions to the existing supply be made the water company shall prepare plans of the same and submit them to the Commissioner of Health for approval.

THIRD: The water company shall maintain a patrol of the watershed at all times to preserve the purity of the waters, more especially when any camp or lumber operation is located on the watershed. The patrolmen shall submit a regular report of the sanitary condition at the camps and lumber operations and any and all dwellings or buildings on the watershed, and the water company shall provide or see that proper sanitary or portable privies be provided and that these receptacles for sewage shall be used and properly maintained to prevent any contamination whatsoever of the surface waters supplied by the Sheffield Water Company to its customers.

FOURTH: If at any time in the opinion of the Commissioner of Health, the water supply of the water works or any part thereof has become prejudicial to the public health, then the water company shall adopt such remedial measures as the Commissioner of Health may approve or suggest.

FIFTH: The water company shall keep records of the operation of the system on blank forms satisfactory to the Department of Health and submit copies thereof whenever required to the Department of Health.

SIXTH: Regular inspections will be made of the system by a Department officer and the State Department of Health may suggest rules and regulations to govern the supply of water to the public in so far as the public health is concerned. The water company shall co-operate with the Department, furnish facilities for inspection and assist in the examination, if this be required.

Harrisburg, Pa., February 11th, 1908.

SHIREMANSTOWN, CUMBERLAND COUNTY.

Shiremanstown Water Company.

This application was made by the Shiremanstown Water Company of Shiremanstown borough, Cumberland county and is for permission to install a system of water works for the supply of water to the public in said borough and to obtain its source of supply from the Riverton Consolidated Water Company at the eastern borough line.

It appears that the Shiremanstown Water Company was chartered on August thirty-first, nineteen hundred and three, for the purpose of furnishing water to the public in the borough of Shiremanstown.

Shiremanstown borough is a small place territorally containing a resident population of about seven hundred, located on the line of the Cumberland Valley Railroad and also along the old turnpike between Harrisburg and Mechanicsburg, and distant about two and a half miles from Camp Hill and Lemoyne boroughs. The latter borough borders on the west bank of the Susquehanna river; intervening is the township of Lower Allen. The Riverton Consolidated Water Company has charter rights to supply water to the public in Camp Hill and Lemoyne and also in Lower Allen township.

Shiremanstown has been a borough since eighteen hundred and seventy-four. It is underlaid by a limestone formation. Dug wells, roof water cisterns and drilled wells furnish the source of domestic water supply at the present time to the inhabitants. Drilled wells are from sixty to two hundred feet deep so it is reported. There are a few of them only, the people paying for the privilege of drawing water from some neighboring well. Sewage is deposited into sink holes drilled into the limestone. Conditions are not altogether assuring. The people are desirous of having running water under pressure in their homes.

During nineteen hundred and seven, so it is reported, the borough council entered into a contract with the Shiremanstown Water Company for pure water to be furnished from the Mechanicsburg Gas and Water Company's plant, a corporation doing business in Mechanicsburg, located several miles to the west. However, it was found that there was no charter authority for the Mechanicsburg cor-

poration to supply water to the public in Shiremanstown, hence during the present season the borough council considered an amendment to the original ordinance whereby permission to the Shiremanstown Water Company to supply water to the borough of Shiremanstown from the Riverton Consolidated Water Company's plant was to be given.

On March nineteenth, nineteen hundred and eight the borough council requested the Commissioner of Health to inform the borough whether the Riverton Consolidated Water Company would supply water to Shiremanstown from the river or from the mountain supply.

The Shiremanstown Water Company has not submitted a plan of its proposed lines of water pipes. The Riverton Consolidated Water Company has filed a plan of a portion of the streets in Shiremanstown, showing size of pipes to be laid therein. According to this plan it appears that the main pipe is to be six inches in diameter and this pipe will be in the main street of the borough and branching off from it are to be lines of four inch pipe in the lateral streets.

The Riverton Consolidated Water Company has two sources of supply, one being from the Susquehanna river opposite the city of Harrisburg and the other from small streams located in the hills in Fairview township, York county, near New Cumberland borough. The former source is subject to sewage pollution. The water is supplied directly to Wormleysburg, Lemoyne and Camp Hill boroughs, and during the summer months, without doubt, a considerable portion, if not all of the water which would be furnished to the Shiremanstown Water Company, would come from the Susquehanna river.

The mountain supply is stored in two reservoirs, the larger of which is known as the Haldeman reservoir. The dam is a small one and it holds about one million gallons. The stream in the spring has a flow of about two hundred and fifty thousand gallons daily, but in the summer time it goes nearly dry.

The Boyer reservoir is not much more than an intake dam. It has a watershed of three-tenths of a square mile while the Haldeman reservoir watershed is slightly less in extent. On it there is only one residence but on the Boyer reservoir watershed there are four residences occupied. The water from the latter is subject to some pollution, especially from a highway and a farm house not owned by the water company. Cattle are pastured in a field abutting the stream. Some attempt has been made by the water company to waste the drainage from the highway and pasture lands and barnyard of the house adjacent thereto, but the improvement has not been perfected and the water in the reservoir is now subject to contamination. These menaces are all subject to correction and the water from both sheds should be preserved in its purity and to a limited extent would furnish a suitable and wholesome supply during all seasons of the year. These reservoirs were first built by the Mountain Water Company with the intention of supplying New Cumberland borough and by an agreement between that borough and the water company, the town has the first right to the reservoir waters. During rainy seasons any surplus may be delivered to the rest of the distributing system and supplied ultimately to Shiremanstown borough, if a connection were made to the system.

The Riverton Consolidated Water Company has asked permission to supply the Shiremanstown Water Company, but this has been withheld because evidence is lacking that said company is capable of furnishing Shiremanstown with an abundance of pure water at all times and under all conditions.

The river water is not suitable in its raw condition to be furnished to any place for domestic use. The Commissioner of Health has ordered the latter company to install a water purification plant.

Provided the Riverton Consolidated Water Company build approved water purification works of a capacity sufficient to furnish the public in its charter territory with water, then it would appear that the plan of the Shiremanstown Water Company to obtain its source of supply from the Riverton Consolidated Water Company would not be prejudicial to public health.

It has been determined that it would be prejudicial to public health to do otherwise than withhold a permit for the present, and the same is hereby and herein withheld to the Shiremanstown Water Company to obtain its supply of water from the Riverton Consolidated Water Company until such time as the Riverton Consolidated Water Company can produce suitable evidence that it can and will and is equipped to supply a pure and wholesome water to the public within its charter territory.

When the water filter plant shall have been constructed by the Riverton Consolidated Water Company under plans approved by the Commissioner of Health, then the Commissioner of Heath will favorably consider the petition of the Shiremanstown Water Company and issue a permit under reasonble conditions and stipulations for said company to obtain its source of supply from the Riverton Consolidated Water Company, provided, however, that if the latter company will submit evidence that it is equipped and will supply the Shiremanstown Water Company with some other suitable supply of pure water other than the filtered Susquehanna River water, then, in that event, the Commissioner of Health will favorably consider such proposition and issue a permit to the Shiremanstown Water Company under reasonable conditions and stipulations.

Harrisburg, Pa., August 18th, 1908.

SHIREMANSTOWN BOROUGH, CUMBERLAND COUNTY.

Shiremanstown Water Company.

This application was made by the Shiremanstown Water Company of Shiremanstown, Cumberland county, and is for permission to obtain a source of supply of filtered water from the Riverton Consolidated Water Company, said filtered supply to come primarily from the city of Harrisburg's water works system.

The Shiremanstown Water Company proposes to use the said filtered water to be supplied to it by the Riverton Consolidated Water Company until the latter can furnish some other pure and wholesome water satisfactory to the Commissioner of Health.

It appears that in a decree issued by the Commissioner of Health on August eighteenth, one thousand nine hundred and eight, the following stipulations were made:

"In view of the foregoing considerations, I have determined that it will be prejudicial to public health to do otherwise than to withhold a permit for the present and I do hereby and herein withhold a permit to the Shiremanstown Water Company to obtain its source of supply of water from the Riverton Consolidated Water Company until such time as the Riverton Consolidated Water Company can produce suitable evidence that it can and will and is equipped to supply a pure and wholesome water to the public within its charter territory."

"When the water filter plant shall have been constructed by the Riverton Consolidated Water Company under plans approved by the Commissioner of Health, then the Commissioner of Health will favorably consider the petition of the Shiremanstown Water Company and issue a permit under reasonable conditions and stipulations for said company to obtain its source of supply from the Riverton Consolidated Water Company, provided however, that if the latter company will submit evidence that it is equipped and will supply the Shiremanstown Water Company with some other suitable supply of pure water other than the filtered Susquehanna river water, then, in that event, the Commissioner of Health will favorably consider such proposition and issue a permit to the Shiremanstown Water Company under reasonable conditions and stipulations."

It further appears on examination by the Department, that the city councils of Harrisburg have in due form enacted an ordinance providing for the sale within the city limits of filtered water by the city to the Riverton Consolidated Water Company for distribution among the company's consumers in its charter territory. This ordinance has been approved by the Mayor.

The Riverton Consolidated Water Company is now engaged in the preparation of detail plans to be submitted to the Commissioner of Health for approval for the construction of its own water purification plant. But meantime, it is the wish of the water company to supply its consumers with pure water.

It has been determined that the proposed source of supply will not be prejudicial to public health, and a permit is hereby and herein issued to the Shiremanstown Water Company to install a system of water works and to obtain its source of supply from the Riverton Consolidated Water Company under the following conditions and stipulations:

FIRST. Detail plans of the water pipes, location of gates, hydrants and drainage facilities shall be filed in the office of the Commissioner of Health showing the system as built at the end of the first year's construction. And thereafter at the close of each season's work plans of the water pipes laid during the year shall be filed in said Commissioner's office, to the end that the State Department of Health shall be always informed of the extent of the water works system and the public use thereof.

SECOND. If at any time, in the opinion of the Commissioner of Health, the source of supply is prejudicial to the public health, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

THIRD. It is expressly stipulated that this permit shall not authorize the use as a source of supply by the Shiremanstown Water Company of any other than the filtered water to be primarily obtained from the city of Harrisburg by the Riverton Consolidated Water Company until the latter company shall have installed its own water purification plant and until it is in a position to furnish a filtered water supply of its own satisfactory to and approved by the Commissioner of Health and the Shiremanstown Water Company shall enter into a contract with the Riverton Consolidated Water Company under terms whereby the latter shall agree to furnish water to the former of a quality satisfactory to the Commissioner of Health.

Harrisburg, Pa., October 15, 1908.

DIRECTORS OF THE POOR, SOMERSET COUNTY.

This application was made by the Directors of the Poor and of the House of Employment of Somerset county, Pennsylvania and is for the approval of plans for an additional source of supply and a permit is issued therefore under the following conditions and stipulations:

It appears that the county home is located on a tract of three hundred and forty-seven acres situate due east of Somerset borough on the Somerset turnpike about two miles from the county seat. The tract is at the summit of the watershed of Coxe Creek, a tributary of the Casselman river.

The main buildings comprise the Administration Hall and Home, the Asylum, the power house and accompanying farm buildings. The first named structure is within one hundred feet of the turnpike and the power house and asylum are grouped about it. The inmates and employees total one hundred and seventy-five.

At the present time the water supply to the three buildings is obtained from two principal sources. One is from a spring on the hill to the east and distant twenty-two hundred and thirty-six feet from the power house. This spring is known as spring number one. The water is collected in a masonry reservoir roofed over and protected from surface wash. This structure is about thirty feet square in plan. The water gushes out from the spring in one corner of the reservoir. The walls are roofed over. The land back from the spring house continues to rise to the summit of the hill. The slope is partly cultivated and partly used for pasturage and at the summit there are woods. The supply is reported to have been satisfactory in quality. A four inch pipe line conveys the water from the reservoir to the power house and to tanks in the upper stories of all three buildings.

The second main supply is located immediately north and about one thousand feet distant from the power house. Spring number two, as it is called, flows out from a porous formation, said to be sandy, about which spring masonry walls have been erected and covered over with stone flagging. In plan these walls form a well about nine feet wide and twelve feet long. They are carried up above the surface of the ground. To the north side there is an opening in the side wall to admit of inspection of the spring water. Two hundred feet to the south is spring number three. It is fourteen feet higher than spring number two. It has been walled up and enclosed and the water is piped to the well at Spring number two. Into this well is inserted the suction pipe of a gas pumping engine, said to have a capacity of twenty-five gallons per minute. This engine raises the water to a three inch force main to the power house and to the tanks above mentioned.

Springs number two and three are about fifty feet lower in elevation than the ground at the power house. They are in a field which slopes quite uniformly northerly. The field is used for pasturage. At times it has been under cultivation. Precaution taken at the springs were afforded to prevent any contamination of the spring water

At the power house there is a deep driven well encased down to rock which has been used as the main supply for the institution until recently. This well was drilled in nineteen hundred and two thereabouts and was put in because of the inadequacy of the other supply. The quantity of water yielded by the deep well has for some unknown cause diminished, so that this supply cannot longer be relied upon, in fact it has failed altogether, so the institution authorities report.

The said authorities now purpose to improve and develop the old spring supply. The four inch pipe line from spring number one to the power house has been laid during the current season to take the place of a pipe of one and one half inches in diameter. Approval of this new line and the supply is asked. Spring number one has a storm flow in wet weather. It was dry during the summer.

The walling up and improvements at springs number two and three and the installation of the pump and the three inch pipe line is about completed. The directors request approval of the said improvements and the source of supply. Formerly the waters used from these springs were carried by hand or hauled to the buildings.

Each of the three main buildings has its own sewer. From the Administration Hall and from the power house there are independent lines of sewers laid southerly under the turnpike over the field about three hundred feet beyond the pike so it is reported and the main building sewer discharges onto a field several hundred feet further from the pike.

The asylum sewer is laid in the opposite direction. It extends northerly and empties into a ravine which forms the head waters of a run which passes north of and below springs number two and three and thence extends westerly into Somerset borough, two miles distant.

There are privies near the asylum on the ground sloping towards springs number two and three The vaults are simply holes dug in the ground.

It has been determined that the proposed sources of supply will not be prejudicial to public health and the same is hereby and herein approved.

FIRST. Every reasonable precaution shall be taken by the Directors to prevent sewage from reaching the proposed sources of water supply. Special attention shall be devoted to the keeping out of the springs of all surface water: If necessary, ditches around the other sides of the springs shall be built to divert surface drainage away from the springs.

SECOND. As a double security all privy vaults on the property shall be laid in masonry and carried up above the surface of the ground to prevent flooding or overflowing. Whenever the contents is removed, it shall be disposed of in a sanitary manner and off of the ground sloping towards the spring.

THIRD. The Directors shall collect monthly samples of water from the springs under written instructions by the State Department of Health and ship these samples of water to the laboratories of the Department for analyses. If at any time, in

the opinion of the Department of Health the water supply of the institution be found prejudicial to the public health, then such remedial measures shall be adopted as the Commissioner of Health may approve or suggest.

The attention of the Directors is called to the probability of improvements being required relative to the distribution of the sewage at the three sewer outlets hereinbefore described. An inspection of the existing methods will be made by a Department officer at an early date.

Harrisburg, Pa., October 29, 1908.

SOMERSET TOWNSHIP, SOMERSET COUNTY.

Gladhurst Water Company.

This application was made by the Gladhurst Water Company of Somerset township, Somerset county, and is for permission to install a system of water works and to supply water to the public.

It appears that the village to be supplied with water by this water company is adjacent to and directly east of the borough of Somerset situated in the central part of Somerset township. It is a community consisting of some twenty-three or more dwellings and having no industrial establishments. The headwaters of Coxes Creek divide this village from Somerset borough. The old Bedford pike passing from Somerset to Bedford passes through the village and it is along this pike on both sides that most of the houses are built and distributed at some distance from each other. There are no railroads in the immediate vicinity, but in Somerset, a branch of the Baltimore and Ohio railroad between Johnstown and the main line passes through and a branch of the Pennsylvania Railroad terminates at this point. There are no coal mines in this vicinity.

The people both in the village and in Somerset obtain a livelihood by means of farming and various commercial pursuits. Somerset being the county seat of Somerset county attracts a great deal of custom and trade.

The whole section is on a high plateau some twenty-two hundred feet above the sea level between the Chestnut Ridge on the west and the Negro Mountains on the east, making a broad expanse of rolling country, some thirty miles wide.

There are no public sewers in the village; the people dispose of their sewage in privies and cesspools. There is one private sewer reported to discharge from one of the dwellings into a tributary of Coxes Creek.

The existing water works consists of springs, the water from which is pumped by means of windmills to a reservoir on the hill from which the water is permitted to run by gravity to the village.

The springs are two in number, one of which is walled up and covered over and completely hidden from view and from which a small pipe carries the water by gravity to the second spring. This spring is also walled up and is covered over with loose boards but is protected from surface wash. Both of the springs are located in a field in the valley between several hills and this field and adjacent fields are under cultivation. They are so protected that cattle cannot get to them and interfere with the purity of the water.

From the second spring two pipes are laid to a well close by over which is built a small pump house and the whole is covered over and the door kept locked. The pipes are three inches and one and one-half inches in diameter respectively, the smaller pipe being in the bottom of the spring and the larger one near the surface. The well is twenty feet in diameter and six feet deep with a six inch blow-out valve and a six inch overflow pipe four and one-half feet from the bottom. The capacity of the well is eleven thousand gallons.

The water is pumped from the well by means of a wind mill and at times when there is no wind a five horse power gasoline engine is put in operation and used as an auxiliary pump. From here the water is pumped through a three inch pipe for a distance of sixteen hundred feet to a small reservoir on the hill one hundred and fifty feet higher than the springs. The reservoir is thirty-five feet in diameter and ten feet deep, built of masonry and covered over with a wooden roof, having two dormer windows opposite each other. These windows are covered with fine mesh copper screens which protects the water from insects and at the same time ventilates it. The capacity is twenty-three thousand gallons. The reservoir is so located on the apex of the hill that surface water drains away from it.

A four inch iron pipe distributes the water to the consumers. This distributing main is about a mile long and at the present time there are nineteen taps on it out of a total number of twenty-three houses in the community. There are fifteen private wells in the village, used either alone or in conjunction with the existing water works.

Besides the existing system and the wells there is a private supply from the second spring to the house of one of the officers of the water company, which supply is pumped from the spring by means of a wind mill to a small reservoir five feet in diameter and ten feet deep constructed of masonry and located on a hill in the rear of this man's lot. This reservoir is covered over and protected from surface drainage. This supply was the original water works and afterwards others became interested and started the new company.

The object of the incorporation of this water company is mainly to supply the immediate vicinity in the village and not to expand into other districts in the township. The fact is that the people who have built houses there pooled their interests to form this company for their own supply and it is not a money making scheme. They have taken great pains to protect the water and to keep it free from contamination.

The method of taking water from the private wells where cesspools and privies are located close by is a menace to public health and it is a dangerous practice.

It appears that the water company was chartered in nineteen hundred and six and built the works the same year so that the application to install water works is for the approval of the existing water works.

It has been determined that the proposed water works system will not be prejudicial to public health and a permit is hereby and herein granted for the installation of such water works under the following conditions and stipulations:

FIRST. That the water company submit a detail map of the springs, wells, pump house, reservoir, distributing main with sizes, location and valves and blow-off forthwith.

SECOND. At the close of each season's work the water company shall make a plan of the water pipes laid in the streets of the village during the year and file the same in the office of the Commissioner of Health, together with any other information that may be required in the operation thereof, in order that the State Department of Health may always be informed of the extent of the water works system and the public use thereof.

THIRD. If at any time in the opinion of the Commissioner of Health, the water works system or source of supply has become prejudicial to public health, then such remedial measures shall be adopted as the Commissioner of Health may advise or approve.

Harrisburg, Pa., July 23, 1908.

SPRINGDALE, ALLEGHENY COUNTY.

Springdale Water Company.

This application was made by the Springdale Water Company of the borough of Springdale, Allegheny county, and is for permission to make extensions to its water pipe system in the streets of the borough.

It appears that Springdale is a new borough having been incorporated during nineteen hundred and six. It is a manufacturing community and residential place, situated on the north bank of the Allegheny river about sixteen miles up stream above Pittsburg. The greater part of the borough is located on a somewhat flat, slightly rolling, tableland or plateau which extends along the entire river front and back to the Pittsburg—Freeport road, which is distant from the river about a quarter of a mile. The West Penn Division of the Pennsylvania Railroad passes through the town along the bank of the river and within three hundred feet of it. Beyond the Freeport road the land rises at a steeper grade, but nowhere precipitous, to an elevation of between two hundred and three hundred feet above the river at the western boundary. Thus the surface of the ground has an easy slope and drainage is good and towards the river. Most of the residences are located along the Freeport road and between it and the railroad. In fact, the dwellings are grouped along either the Pennsylvania Railroad and Colfax road adjacent to it, or along the Freeport road. The land between these two thoroughfares is partly built up.

The present population is estimated to be about two thousand. Many of the property owners do business in Pittsburg, riding to and fro daily. There are three industries in the town.

The Heidenkamp Plate Glass and Mirror Company employ about three hundred hands. The plant is located in the central part of the borough on the river bank near Colfax street. Drinking water for the shop is obtained from neighborhood wells and is carried as needed by persons employed for that purpose. Water for industrial purposes is secured from the river. The sewage from the property is deposited in the Allegheny.

The Pennsylvania Glue Company employs about one hundred and fifty hands. The plant is located on the river bank, immediately above the government dam, which is in the upper central part of the borough. Drinking water is obtained from drilled wells located on the premises. The industrial wastes are treated in a sedimentation tank and the sewage is discharged into the river.

The Pennsylvania Swedish Iron Company's works are small and are located along the Freeport road in the extreme western part of the borough.

The people quite generally obtain their drinking water from wells drilled on the premises. There are a few dug wells. Most of the drilled wells are cased to a depth of from sixty to eighty feet. There are a number of springs in the borough, several of these being of a considerable size. One of these is owned by R. L. Elliott. It is the source of supply to the Elliott Nursery Company and to the Neff Green Houses and also to forty-seven families. The spring is located in a ravine about fifteen hundred feet north of the Pittsburg-Freeport road near Maple street

in the western part of the borough. The spring is bricked in, covered and the water is piped to a brick tank and from there to an iron tank of about seventy-five barrels capacity, and thence to the consumers. The brick tank is located about one hundred feet from the upper end of the ravine and the iron tank about fifty feet below this and also in the ravine. Above the spring on higher ground are located several dwelling houses. At present none is nearer than six hundred feet. The houses are situated on the ground which slopes in the opposite direction from the spring. Should the land in the immediate vicinity of the ravine be settled, there would be possibility of contamination of the waters of the spring. Most of the forty-seven dwellings mentioned are comprised in the Heidenkamp group of tenements located near Colfax spring adjacent to the glass works. There are also a few families in the immediate vicinity of the spring using this water. The green houses and the nursery are below the Pittsburg-Freeport road.

The Springdale Water Company was chartered on April twenty-seventh, nineteen hundred and five, for the purpose of supplying water to the public for commercial and domestic purposes in Springdale township, Allegheny county, out of which township Springdale borough has since been incorporated. Prior to this charter the works were constructed by individuals, so it appears. As it now exists, the system comprises a pumping plant, a drilled well, a storage tank and the distributing system of pipes.

The pumping plant is located about one thousand feet north of the Pittsburg-Freeport road on Murtland avenue, on land owned by the water company. This place is on a terrace at the top of a steep slope. Northerly the slope continues, but at a more gradual ascent, for about a quarter of a mile, to the borough line. The pump house is a wooden structure fifteen feet wide, twenty feet long, and in it is located a two hundred and fifty barrel wooden tank, into which the water is pumped and stored for distributing purposes. There is a small gas engine used to lift the water from the well. This well is located in one corner of the building. It is drilled seventy feet deep and is encased in iron tubing. The water is pumped about four hours daily. This amount serves to meet all present requirements.

To the west of the pump house there is a ravine in which there is a small run about thirty-five feet from the house and about thirty feet lower in elevation. About one hundred yards to the east of the pump house there is another ravine not so deep. Both ravines have a general north and south direction. In the section formed by these ravines there is at present only one building, an old barn. It is located about a quarter of a mile above the pump house. Near the barn there is a small pumping station used by the Moyer Sand and Gravel Company to supply water to a sand quarry near the top of the hill which drains into the ravine. On the slope of the west ravine there is a farm house.

There are two private dwellings in the vicinity of the water company's pumping station. These face on North street. There are out-houses on the property.

The distributing system comprises thirty-eight hundred and fifty feet of two inch iron pipe.

The company proposes to lay a four inch pipe line the whole length of the Pittsburg-Freeport road in the borough and also to make extensions to the street pipe system from time to time as necessity may require. At present there are reported to be thirty consumers on the company's system.

While it is at once evident that the water works system is limited and is not adapted to supply the entire borough with any considerable amount of water, and while it is also apparent that if the water company should purpose at any time to supply the industrial plants or to afford fire protection it would be necessary to lay entirely new lines of pipe of larger diameters in the streets, nevertheless, it cannot be determined from the evidence now before the Department that the existing supply for drinking purposes is prejudicial to public health. Undoubtedly, the company will in the proper time and when there is a prospect of adequate revenue, introduce material changes in the water works system.

It has been determined that the existing supply of water to the public and the water works system is not prejudicial to the public health, and that the proposed extensions thereof will not be prejudicial to the public health and the same are hereby and herein approved and a permit granted therefor, under the following conditions and stipulations:

FIRST. That at the close of each season's work plans of the pipes laid during the year shall be prepared and filed in the office of the Commissioner of Health, together with any other information in connection therewith that may be required, to the end that the Department of Health shall always be informed of the full extent of the water works system and the public use thereof.

SECOND. The water company shall not increase its existing source of supply, drill new wells, build new reservoirs and pumping facilities, or otherwise make extensions to the water works other than those hereby and herein approved, without first submitting detail plans thereof and making application for approval as provided by law.

THIRD. If at any time in the opinion of the Commissioner of Health the water works system or the source of supply shall become prejudicial to the public health, then such remedial measures shall be adopted and provided as the Commissioner of Health may approve or advise.

Harrisburg, Pa., October 5, 1908.

STATE COLLEGE BOROUGH, CENTRE COUNTY.

University Water Company.

This application was made by the University Water Company of State College borough, Centre county, Pennsylvania, and is for permission to obtain a source of supply and to build water works to supply water to the public in the township of Ferguson and the township of College, said townships being in Centre county.

It appears that the University Water Company is the present name given by authority of law on July third, nineteen hundred and eight, to a corporation organized under the laws of the State and approved by the Governor on the fifth day of February, nineteen hundred and seven, under the name and title of the "Farmers Rural Water Company of Ferguson Township."

The purpose of the company is to supply pure water to the public in all that portion of Ferguson township, to wit: "Beginning at a stone on the division line between Harris and Ferguson townships, at the foot of Tussey Mountain; thence west along the foot of said mountain four hundred and fifty rods to stone; thence north one hundred rods to the Matternville road; thence following said road north five hundred and fifty rods to junction of said road with the Gatesburg road; thence along the Gatesburg road east five hundred and forty-eight rods to the division line between College and Ferguson townships; thence by said line and the line between Harris and Ferguson townships south twenty-four degrees east, six hundred and eight rods to the place of beginning."

Ferguson township lies west and southwest of State College borough and it concludes a portion of the State College farm property. The Gatesburg road, called College avenue in the borough, extends southwesterly in the township and the Matternville road is laid out at right angles to the Gatesburg road and is parallel with the boundary line between the borough, Harris and College townships to the east and Ferguson township to the west. Within this district is a territory occupied by farms, the owners of which desire to obtain a public supply of water. Since the territory is sparsely populated, the conditions for the organization of the water company for this purpose are exceptional. The country is a high plateau underdrained by a stratum of exceedingly fissured limestone. Considerable difficulty is experienced in obtaining water from wells, owing to the depth, and so the citizens have to rely largely on cisterns for their drinking water. This supply has the additional advantage of no small importance of being soft in quality. Some of the farmers have had to haul water considerable distances during dry seasons and there is need, therefore, for a reliable water supply in this scattered rural community.

The source of supply selected is a small stream rising in what is known as "Tussey Mountain," said mountain being the boundary line between Centre county and Huntingdon county. The geological structure is sandstone formation and the waters delivered from the mountain are correspondingly soft and pure. The stream flows in a northerly direction to meet a small tributary of Spring Creek, which eventually is joined by Logan Branch at Bellefonte borough and empties into Bald Eagle Creek. The latter joins the west branch of the Susquehanna river just below Lock Haven borough. These streams, with the exception of the Tussey Mountain Brook, are supplied by wonderful springs in the valleys flowing from subterranean passages. The waters are naturally hard.

It is the purpose of the water company to erect a dam and storage reservoir on the brook at what is known as Musser's Gap. This dam is to be a concrete structure and when completed its entirety will store one million, two hundred and fifty thousand gallons, approximately, and have an area of about one-quarter of an acre. The watershed above the dam is steep and covered by heavy forests. There are no habitations upon it. The area is approximately four-tenths of a square mile. The chief owner has for himself and heirs agreed not to denude the watershed. Records of the yield of the brook of Musser's Gap taken during drought show a flow of about seventy-four thousand gallons per day as the minimum.

The maximum depth of water with full reservoir will be twenty feet. Soil or organic matter is to be stripped from the bottom of the area to be flooded.

A twenty-four inch drain with valve is to be provided in the dam for drainage. The structure is to be constructed in a substantial way and is to be a spill-way dam, approximately ninety feet in length. From it an eight inch gravity supply main is to be laid across country in the charter territory above described and branch lines are to be laid from it to farm buildings on the various farms through which the main line is to pass.

The height of the water in the reservoir will be three hundred and eighty-eight feet above the campus grounds of the college in the borough about four miles distant.

It appears that the authorities of the State College were not satisfied with the present supply which is obtained from the State College Water Company, a corporation also supplying the borough. Not only is this company's supply the subject of some complaint, both as to quality and quantity in the summer time, but the pressure is not always sufficient and satisfactory. The college authorities, therefore, in looking about for a suitable supply in addition to its own supply from a driven well on the premises, the waters of which are exceedingly hard, concluded the Tussey Brook source contemplated by the said Farmers Rural Water Company

was the only available and suitable source of supply for the college. And so the water company designed its works with the understanding that water would also be furnished to the college, the intention being to supply this water at the Ferguson township line within the charter territory of the water company.

It further appears that some of the officers of the college and prominent citizens interested in the welfare of the institution acquired the controlling interest in the said Farmers Rural Water Company and changed the name thereof to that of the University Water Company. The works have not been built, but it is the intention of the company so to do as soon as the approval of the plans shall have been given by the Commissioner of Health.

It has been determined that the proposed water works and source of supply will not be prejudicial to public health and a permit is hereby and herein granted therefor under the following conditions and stipulations:

FIRST. Detail plans of the dam, pipe line and branches shall be filed in the office of the Commissioner of Health upon completion of the system, showing how said works have been constructed.

SECOND. Ample drainage facilities along the line of the supply main shall be provided to admit of the ready emptying of such line in case of necessity.

THIRD. If at any time, in the opinion of the Commissioner of Health, the source of supply or the water works system or any part thereof is prejudicial to public health, then such remedial measures shall be adopted as said Commissioner may approve or advise. If any lumber operatons should be undertaken on the watershed, or if any habitation or other source of pollution is established on the watershed at any time, the water company shall immediately notify the Commissioner of Health and co-operate with the State Department in the enforcement of sanitary regulations to safeguard the purity of the waters used as the source of supply to the public by said company.

FOURTH. If public health shall require it, the State Board of Health may establish rules and regulations for the operation of the water works system and the water company shall be bound in accepting this permit to abide and observe such rules and regulations in so far as they shall relate to public health matters. If any additional pipe line in the charter territory should be laid, at the close of each season plans of such additional pipe line laid during the year shall be filed in the office of the Commissioner of Health, together with any other information in connection therewith that may be required, to the end that the Commissioner of Health shall always be informed about the extent of the water works and the use thereof.

Harrisburg, Pa., July 23, 1908.

STEELTON BOROUGH, DAUPHIN COUNTY.

Board of Water Commissioners.

This application was made by the borough of Steelton, Dauphin county, and is for permission to make an emergency connection between the low and the high lift pumping engines at the borough's water works pumping station.

It appears that the application was made on behalf of the Water Board by its Consulting Engineer, and said application reads as follows:

"The Water Commissioners of the Borough of Steelton wish, in arranging the piping in the borough pumping station in accordance with the plans for the filter plant, which were approved by your Department in the early part of last summer, to add an emergency connection between the discharge pipe from the low lift pumps which pump the raw water to the filters, and the suction pipe of the high lift pumps which pump the filtered water to the city. The desirability of this connection, from the point of view of the Water Commissioners, is that the river bank at Steelton is not as high as the highest flood level, and consequently the pit in which the centrifugal pumps will stand is likely to be flooded so that the pumps might be completely submerged at times. Under these conditions these pumps could not be run, and a shortage of water might occur if a severe conflagration should visit the city.

"The high lift pumps, which pump water to the reservoir in the city, stand at a sufficiently high elevation not to be interfered with by floods in the river, and if there were a cross connection between the discharge pipe from the centrifugal pumps and the suction pipe to the high lift pumps, river water could be drawn through the centrifugal pumps by the high lift pumps if necessary.

"The manner of making the connection, as suggested by the President of the Board of Water Commissioners, is to place a "T" in the discharge pipe from the centrifugal pumps and also one in the suction pipe from the high lift pumps, and provide a special elbow, which could be bolted to the flanges of these two T's, in case of necessity; ordinarily this special connecting piece will not be in position, but the opening of the T's will be closed tight with blank flanges bolted on.

"There is very little likelihood that this emergency connection will ever be required, as the city reservoir holds a sufficient supply of water to tide over any flood, providing no unusual draught of water were made, such as might occur during a very extensive conflagration, or as the result of a serious break in some of the street mains during a flood.

"I am enclosing a blue print which shows the proposed method of connection, as suggested by the Water Commissioners, having notified them that I cannot put in this connection without permission from the Commissioner of Health, in as much as the original plans had been approved and I had no authority to change them.

"It is desired to place the order for all the piping in connection with the low lift pumps as soon as possible, and your early consideration of this connection is respectfully requested, so that the plans may be completed and the pipe ordered."

The making of this connection is herein approved under the condition that it shall in no way effect the stipulations in the permit issued by the Commissioner of Health to the borough of Steelton dated September eleventh, one thousand nine hundred and seven, and that the proposed connection shall not be used except in some great emergency like a great conflagration.

Harrisburg, Pa., February 26, 1908.

STEELTON, DAUPHIN COUNTY.

This application was made by the borough of Steelton, Dauphin county, Pennsylvania, and is for approval of detail plans for a new water works intake.

On September eleventh, one thousand nine hundred and seven, the Commissioner of Health issued a permit to the borough of Steelton to increase its source of public supply and to make extensions and improvements to its water works system under certain conditions and stipulations among which was the following:

"If practicable, the borough shall during the present low stage of the river forthwith proceed to caulk and render tight all joints on the existing intake pipe and plans for a completed intake well and pipe shall be made and submitted to the Commissioner of Health for approval during the current year."

In conformity with this requirement the borough endeavored to make the pipe line tight but failed. It therefore, during the current season replaced the old pipe with a new one thirty inches in diameter.

The new intake was built partly as an emergency work because the extreme low water of the summer made it impossible for the securing of any supply from the river through the old intake.

As now constructed the new thirty inch cast iron pipe begins at the point near the bank of the river where the old twenty-four inch pipe laid in place in anticipation of extension across the river terminated. This old pipe is fully described in the said permit of September eleventh, nineteen hundred and seven.

From this point the new thirty inch cast iron pipe is laid in a trench slightly beneath the present rock bottom of the river a total length of eleven hundred and thirty feet to the new intake located near the bank at the island opposite the pumping station. In this total length the thirty inch pipe has an ascending grade towards the inlet of six inches. At the shore line, near the pumping station there is a twenty-four inch gate valve on the pipe.

The intake at the end of the thirty inch pipe is similar in construction to the new intake on the end of the river pipe at the Harrisburg filtration plant. The top of the intake opening is seventeen inches below the low water mark of this season and there is no record of a lower water mark than this in the life time of any living person.

It has been determined that the interests of the public health are amply safeguarded by the new intake and the plans are hereby and herein approved and a permit issued therefor.

Harrisburg, Pa., October 15, 1908.

SWATARA TOWNSHIP, DAUPHIN COUNTY.

Rutherford Heights Water Supply Company.

This application was made by the Rutherford Heights Water Supply Company of Swatara township, Dauphin county and is for permission to obtain an additional source of supply from a spring known as Paxtang in the said Swatara township.

The Rutherford Heights Water Supply Company is duly chartered under the laws of the State to supply water to the public in Swatara township. Its source of supply was at first confined to the Swatara Creek at a place shown on the plan submitted by said company and filed in the office of the State Water Supply Commission, March thirteenth, nineteen hundred and seven. Subsequently, on October twenty-seventh, nineteen hundred and seven, the said company secured an amendment to its charter whereby its source of supply may be taken from the Swatara Creek at Hummelstown, at the same point from which the Hummelstown Consolidated Water Company draws its supply. It is the intention of this latter company to filter the creek water and sell it to the former company and it was with this understanding that the modified charter was granted.

It appears that on August sixteenth, nineteen hundred and seven, the Rutherford Heights Water Supply Company asked permission to obtain a temporary supply of water from the Eastmere Water Company, a duly incorporated company supplying water to the inhabitants of the village of Eastmere, a suburb of Harrisburg within Swatara township. This request was denied by the Commissioner of Health on the ground that the charter confined the Rutherford Heights Water Supply Company to the Swatara Creek as a source.

It now appears that pending the erection of filtration works and machinery for the treatment and supply of Swatara Creek water through the said company's mains, yet to be built in compliance with the terms of a permit issued by the Commissioner of Health on July twenty-second, nineteen hundred and seven to the Rutherford Heights Water Supply Company in which it is specified "that before the proposed water works system be constructed and used, detail plans thereof shall be prepared and submitted to and approved by the Commissioner of Health as provided by law," the inhabitants of the village of Rutherford Heights are insistent upon an immediate supply of pure water, and therefore, the said Company request permission to utilize the said "Paxtang Spring" as a temporary source of supply.

Paxtang Spring otherwise known as Rutherford Spring, is located on the farm of the heirs of S. S. Rutherford at the point about two hundred feet south of the right of way of the Philadelphia and Reading Railway and perhaps twenty-five feet west of the road entrance to Paxtang Park. Within a radius of a quarter of a mile is located the village of Paxtang, of perhaps twenty-five houses and one hundred and twenty-five residents. The dwellings are provided with modern plumbing and the drainage is mostly to cess-pools. At various places an outcrop of limestone shows that there is a pitch in the strata towards the southeast, and if this be the regular formation, it indicates the possibility of the underground drainage of from possibly twenty properties towards the Paxtang Spring.

The spring itself issues from the rock beneath a small stone spring house. The house has two floors. On the ground floor are the appointments of a small dairy. The platform is almost on a level with the water of the spring, and there is danger of pollution brought in by the shoes and left on the platform. Milk cans are rinsed out into the waters of the spring or the overflow thereof.

The flow is very copious and it is reported that it has never ceased even in a protracted dry period. On the day of the Department's inspection the outflow was measured to be two million gallons. This is proof that the contributing area is of a large extent and the geological formation being limestone leads to the conclusion that were the surface area from which these ground waters are gathered thickly populated, a very pronounced evidence of contamination would follow.

On the second floor of the spring house one of the farm attendants lives. The nearest building is the farm house two hundred feet north of the spring.

From the west where there is a cart road surface, drainage can reach the spring so that if the spring water be used temporarily, a source of supply, it should be walled up and every precaution taken to exclude surface water or any other surface pollution.

A part of the overflow of the spring is used to operate a hydraulic ram by means of which water is raised to the Rutherford farm buildings and mansion.

The spring also furnished a three inch pipe line which conveys water to Paxtang Park.

A test of the spring water made by the Philadelphia Clinical Laboratory on October fourteenth, nineteen hundred and seven, showed it to be potable. It would appear possible to adopt precautions to preserve the purity of this spring from surface contamination, but whether the waters be subject to under ground pollution is a question which needs extended investigation and possibly constant examination. The topographical conditions are suspicious. A temporary right to use this water might be approved by the Commissioner of Health on presentation of satisfactory plans for the collection and distribution of the water. No such plans have been submitted by the Rutherford Heights Water Supply Company. Furthermore, the charter limitations of this company as to this source at present preclude it as a possibility. A still further modification of the company's charter would appear to be necessary.

It has been determined that the application of the Rutherford Heights Water Supply Company to use Paxtang Spring is not properly before the Department of Health, since this source is precluded by the company's charter. If a modified charter be obtained, then the Commissioner of Health may favorably entertain such an application. However, the supply would not be favorably recommended as a permanent source for any water company because of the uncertainty as to the quality of the water. The district is rapidly increasing in population and the time cannot be far distant when sewage pollution will be likely to manifest itself at the Spring. If observations relative to the pollution of underground waters coming from populated areas in limestone districts elsewhere are a criterion by which to judge.

Harrisburg, Pa., January 16, 1908.

SWATARA TOWNSHIP, DAUPHIN COUNTY.

Paxtang Consolidated Water Company.

This application was made by the Paxtang Consolidated Water Company of Swatara township, Dauphin county, and is for permission to obtain an additional source of supply from the spring known as Paxtang Spring in said township.

The Paxtang Consolidated Water Company was originally called the Paxtang Water Company, which company was chartered in eighteen hundred and ninety-five for the purpose of supplying water to the village of Paxtang and adjacent thereto in Swatara township. In nineteen hundred and six the name of this company was officially changed to its present name. The water company's original supply came from a drilled well on the hill to the north of the village of Paxtang, but later this source proving inadequate the company purchased a supply from the Eastmere Water Company, a duly incorporated company supplying water to the inhabitants of the village of Eastmere, a suburb of Harrisburg, in Swatara township, the Eastmere Water Company purchasing its water in turn from the city of Harrisburg at the city limits. Recently the Harrisburg supply was refused to the Eastmere Water Company and hence to the Paxtang Consolidated Water Supply Company; consequently, the latter company had to resort to the original well supply and the former was obliged to purchase of the latter. The well is inadequate for these purposes.

In nineteen hundred and seven the Rutherford Heights Water Supply Company was chartered under the laws of the State to supply water to the public in Swatara township. The charter rights limited the company to the Swatara Creek as the source of supply. Later this was modified so as to enable the company to obtain water from said creek at Hummelstown.

This company applied to the Commissioner of Health for permission to install a system of water works for the supply of water to the public in the township of Swatara, Dauphin county, and represented that it purposed to supply the public in the villages of Rutherford Heights, Oberlin, Enhaut and New Benton, all situated in said township, and also to supply the public in other parts of said township through which the company's pipe lines pass in reaching these villages or from which sufficient revenue might be secured to warrant the laying of additional pipe lines. The permit was granted by the Commissioner of Health under certain conditions and stipulations, one of which was substantially that before the proposed water works system be constructed and used, detailed plans thereof should be prepared and submitted to and be approved by the Commissioner of Health as provided by law, and among other things that the plans shall include designs for a water purification plant. Plans for the purification of the Swatara Creek water at Hummelstown have been approved by the Commissioner of Health and the work on the construction is underway. This plant is owned by the Hummelstown Consolidated Water Company, which proposes to furnish filtered water to the Rutherford Heights Water Supply Company for distribution throughout Swatara township.

Pending the construction of this filtration plant the Rutherford Heights Water Supply Company on August sixteenth, nineteen hundred and seven, asked permission of the Commissioner of Health to obtain a temporary supply from the Eastmere Water Company but the request was denied because the charter of the Rutherford Heights Water Supply Company confined it to the Swatara Creek source.

After this refusal by the Commissioner of Health, and on October nineteenth, nineteen hundred and seven, the Rutherford Heights Water Supply Company applied for permission to use the stream known as Paxtang Spring as an additional source of supply, but their request was again denied by the Commissioner of Health on the ground of limited charter rights. In the decree of refusal it was specifically stated, however, that if a modified charter were to be obtained, the Commissioner of Health would favorably entertain such an application, but the supply would not be favorably recommended for a permanent source.

Paxtang village and vicinity consists of about forty dwellings and is located in the northwestern part of Swatara township on the Philadelphia and Reading Railway (Lebanon Valley Branch) about two miles east of the passenger station in Harrisburg. It is purely a residential section accessible to Harrisburg by railroad and trolley. The region surrounding the village is farming district and the whole underlaid by a limestone formation. The dwellings in the village are mostly provided with modern plumbing and discharge their sewage and waste in cesspools, there being no sewers to the waters of the State. Outcrops of the limestone formation show the shale pitching toward the southeast; and hence the drainage of the village and of the eastern suburbs of Harrisburg is in the same direction and presumably towards the Paxtang Spring.

The present drilled well supply is obtained on the hill back of Paxtang village near the cemetery and is collected by means of a small gas pumping engine. A two inch wrought iron force main discharges from the pump to a wooden storage tank twelve feet in diameter and seven feet high which rests on a masonry foundation which is about six feet from the ground and is roofed over. A supply main leads from the tank to the village. The company has not submitted plans of the pump house and well and tank lay-out. The report states that there are about twelve

hundred feet of six inch wooden pipe supply main from the tank to the village and connected with it about one thousand feet of six inch cast-iron pipe about four thousand feet of four inch cast iron pipe and that about two hundred inhabitants are furnished with water. It is reported that the well is one hundred and seventy feet deep.

The proposed supply is to be taken from Paxtang Spring, sometimes known as Rutherford Spring, which is located on the farm of the heirs of H. S. Rutherford at a point about two hundred feet south of the right of way of the Philadelphia and Reading Railway and about twenty-five feet west of the trolley road entrance to Paxtang Park. It issues from the limestone rocks from beneath a small spring house, which has two floors. On the ground floor which is on a level with the water in the spring are the appointments of a dairy. It is here where milk is cooled and the cans are rinsed out into the waters of the stream or its overflow. A platform almost on the level with the stream extends two-thirds of the way across the water and is used to stand on while manipulating the milk cans. There is danger of polluting material being brought in by the shoes and left on the platform, from whence it might be washed into the water. The second floor of the spring house was formerly occupied by a man employed in the vicinity. Adjacent to this floor, but on the outside, is a small chicken coop in use. About two hundred feet to the north is the farm house.

There is a cart road from the farm buildings to the west of the spring which drains directly into the water of said spring.

The flow of the spring was estimated on the day of the Department inspection to be about one million gallons per twenty-four hours, and it is reported that this flow has never ceased even in times of drought, showing that the water comes from a much larger area than the immediate surroundings. A part of the overflow of the spring is used to operate a hydraulic ram by means of which water is raised from said spring to the mansion and other farm buildings. Immediately below the spring is Paxtang Park, a pleasure resort for picknickers and day visitors. This park is shut off from the spring by means of a fence. A three inch pipe line conveys water from the spring to the resort.

The topographic features connected with the Paxtang spring are such as to cause suspicion. The close proximity of the village one quarter of a mile to the north, the dip of the limestone from the populated district toward the spring together with the large body of water issuing therefrom would be just cause for such suspicion.

The petitioners have not submitted any plans showing the details of how the water is to be taken from the Paxtang spring and furnished to the public. But it is understood that the suction pipe of the pump is to be inserted in the spring, the object being to draw the water from a point above where it may be subject to any possible contamination from the immediate vicinity. From the pumps a temporary main will be laid to the turnpike and connected with the supply main there. Said main in this thoroughfare is a twelve inch water pipe extending westerly to Eastmere and easterly beyond Paxtang village in Swatara township.

It has been determined that the proposed additional source of supply will not be prejudicial to the public health, and plans therefor are hereby and herein approved under the following conditions and stipulations:

FIRST: That the company shall prepare a plan of Paxtang village and its surroundings, showing the streets, general location of buildings, water pipes, sizes, gates and hydrants, the location and details of the drilled well supply and the details of the additional source herein approved, and the pump and supply main layout in connection therewith as built, and shall file the same with the Commissioner of Health within two months from the date of this permit.

SECOND: The State Department of Health will make bacteriological tests of the water of the spring and if at any time in the opinion of the Commissioner of Health the water supplied by the Company has become suspicious and prejudicial to public health, thereupon the water company shall adopt such remedial measures as the Commissioner of Health may advise or approve.

THIRD: This permit shall cease at the end of the current year. If at that time the filtered Swatara Creek water supply is not ready for introduction into Swatara township territory as contemplated, then the Commissioner of Health may extend the time in which Paxtang Spring may be used by the Paxtang consolidated Water Company, but it is the intention of the State to cause the abandonment of both the present drilled well supply and the additional Paxtang spring supply upon the introduction of the filtered Swatara Creek water into the district:

FOURTH: It is stipulated that this permit is contingent upon the water company having acquired full right to enter upon and appropriate the waters of the Paxtang Spring as proposed.

FIFTH: It is also specially stipulated that the intake shall be located in the spring at a point where there shall be no danger of pollution. Also the occupancy of the spring house by man or beast is prohibited. The hen coop shall be removed and the spring placed in the best of condition.

Harrisburg, Pa., June 16, 1908.

TOWANDA, BRADFORD COUNTY.

Towanda Water Works Company.

This application was made by the Towanda Water Works Company of Towanda borough, Bradford county, and is for permission to extend its water works system to supply water within its charter territory.

It appears that the Towanda Water Works is a duly incorporated company chartered by the State in eighteen hundred and seventy-nine for the purpose of building and managing a system of water works for supplying the public general to Towanda and vicinity.

Towanda is the seat of Bradford county and is located near the centre of the said county. It is bounded on the east by the North Branch of the Susquehanna river and on the other sides by Towanda and North Towanda townships. In eighteen hundred and ninety the borough had a population of four thousand one hundred and sixty-nine, and in nineteen hundred it was four thousand six hundred and sixty-three, while at the present time it is estimated to be about five thousand. The municipality is built on a hillside, sloping toward the river and has excellent natural drainage toward the river. It is somewhat of a manufacturing place, and the people find a means of livelihood at the toy factory, employing one hundred and twenty-five hands, the silk mill, employing twenty-five hands, besides numerous other smaller industries and local pursuits. There are three railroads entering the borough which also give employment to a number of the residents of this town, especially the Lehigh Valley, whose main line between New York and Buffalo passes through Towanda. This railroad has large car shops at Sayre eighteen miles north where many of the Towanda men are employed, a special train carrying them to and from their work. The other two roads are the New York and Susquehanna and the Bowmans Creek Branch of the Lehigh Valley Railroad. The surrounding territory is hilly and mountainous and of a glacial deposit, the valleys and tops of the hills being given to agricultural pursuits. In the immediate vicinity of the borough there are large tracts of flat land which are devoted to tobacco raising. The farmers in the rural districts thereabout make a specialty of dairy produce and send it to the New York markets. At one time lumbering was the chief industry but the dissipation of the timber has made this means of livelihood of minor importance.

A short distance below the borough the Towanda Creek discharges into the river. This stream has a watershed area of two hundred and eighty-four square miles and drains the greater part of the southwest section of Bradford county. It is made up of the main stream proper and three branches; named in order, these are the North Branch, Shrader Branch and the South Branch, the former entering the main stream from the north and the latter two from the south. On this water-shed there are four boroughs having a total population of twenty-five hundred and a township population in the neighborhood of fourteen thousand. The stream is twenty-seven miles long, it flows through an agricultural district eastwardly to the river.

The South Branch heads in the divide between Bradford county and Sullivan county and flows almost due north for a distance of fourteen miles to the main stream at the borough of Monroe. The stream is paralleled throughout its course by the Bowmans Creek Branch of the Lehigh Valley Railroad. The borough of New Albany, having a population of about five hundred, is located on this stream, eight and a half miles from its mouth. For a greater part of the distance of its course, the stream flows through a narrow valley and it has the appearance of a mountain stream.

The present supply of water is obtained by gravity from Eilenberger springs located seventeen miles south of Towanda, adjacent to the South Branch near its source and from a tributary of said stream about midway between the borough and these springs. From these springs the water flows through a small reservoir close by thence through ten inch cast-iron pipe for seventeen miles to Towanda. It receives the auxiliary supply through an eight inch line at the mouth of Satterlee Run. At Towanda a part of the water is received in two storage reservoirs, the remainder being distributed throughout the town.

The Eilenberger Springs, from whence the greater part of the water supply is received, are located at the base of a ridge and about a mile south of the village of Laddsburg in Albany township. They are several hundred feet east of the South Branch. Immediately to the east of the springs and up the side of the ridge there is a farm land used principally for pasture. The springs are enclosed on all sides by cemented stone walls about four feet high, the tops of which are slightly above the level of the ground. This structure is thirty feet long, three and a half feet wide, four feet deep and is covered over with flag stones having cemented joints. An air pipe extending about five feet above the stone covering affords means of ventilation while a trap door with an iron cover, kept securely locked provides means of entrance. This basin is well protected from any surface drainage or malicious pollution. From the lower end a twelve inch terra cotta pipe emerges along the bottom and conveys the water through about two hundred feet of open jointed terra cotta pipe, thence through about three hundred feet of jointed pipe to a small reservoir in the ground, six feet wide by seven feet long and at least eight feet deep from the surface of the ground. This box is built of stone and cement and covered over by

a cement roof extending to a ridge, the ridge running the whole length of the box. This sloping roof is about four feet or so higher than the surface of the ground and has an iron door in one side of it large enough for a person to crawl through. All parts of this receptacle are closed and the doors kept locked. A twelve inch terra cotta pipe discharges into this reservoir from the spring and a ten inch cast-iron pipe having several feet of fine mesh strainer pipe and a gate valve located in the reservoir, conveys this water to Towanda.

There is an emergency intake consisting of an eight inch iron pipe extending from the east bank of the South Branch to the twelve inch line at the upper end and outside of the reservoir. The length of this intake is about thirty feet. At its upper end there is a wooden plug attached to a chain, the plug being inserted in the end of the pipe or taken out at will, thereby permitting the South Branch water to enter the system by gravity. There is a valve inserted in the ground at a point where the emergency intake might join the supply line which is reported to control the amount of water taken in through this intake.

At a point a short distance above the intake to the creek there appears to be some form of communication between the creek and the pipe line from the springs above the reservoir. This is in a form of a ditch which is said to have been filled in with stones and gravel so as to form a natural filter, the water being received from the edge of the creek bank, thence through the natural filter to the supply line. It is reported by an officer of the water company that this means of supply has been abandoned.

Another means of helping the main supply line was to underdrain some of the low land adjacent to the creek by perforated open joint tile drains and conduct this water to the main line.

The vicinity of the springs, the reservoir and entrance thereto has been purchased to the extent of about twenty-seven acres by the water company. The house on the property is vacated. This is reported by an officer of the water company to have been at the suggestion of the old State Board of Health.

The South Branch Creek at this place has the appearance of a small meadow stream and has pasture land on either side, so that cattle and other livestock can wade or wallow in the stream at will. The stream rises in hills, forms into rivulets, then unites to form the main stream. The area of the watershed above the Eilenberger Springs is in the neighborhood of ten square miles and contains a number of farm houses having their pig pens, barnyards and some privies draining into the stream, thereby causing the stream to be dangerous as a means of water supply for domestic purposes. A railroad having several local passenger trains a day, parallels the stream for a short distance and crosses a small tributary flowing into the stream above the emergency intake.

The stream from which the auxiliary supply is taken, is from Satterlee Run, a tributary of the South Branch. An eight inch pipe extends up the valley of this run from the ten inch supply line to Towanda a distance of about one mile and terminates in the run with a perforated tee pipe having three eight inch holes. The intake consists of a number of loose stones thrown across the run forming a crude dam and a second series of stone extends from the middle of the first, blocking up the stream, and across to the north bank a distance of some twenty-five feet. The enclosure between the bank and the blocking being somewhat lower than the bed of the stream forms a natural pool through which the water is received into the pipe line. The flow of the water into the line is greatly impeded at times on account of leaves blocking the openings in the screen intake and being held in place through suction.

The watershed of the run is a narrow valley with high ridges on either side and having an area of about five square miles the greater part of which is densely wooded with second growth timber. There is a privy not over forty feet from the banks of the stream, one quarter of a mile above the intake. This belongs to a small farm in the valley, the occupant of which at the time of the Department's inspection reported that the water company had purchased this farm and he contemplated moving away at once. Further up the valley there is another farm on a tributary to the main run, the owner of which stated that at one time they had a privy on the premises but it toppled over and since has not been replaced. The deposits and excrement are placed on surrounding ground. This man reports also that there are at least three other habitations on the water-shed. This method of disposing of excrement is dangerous at any time and especially so on a water-shed with steep sides draining directly into the stream such as this one is. The stream is flashy and during time of heavy rain becomes exceedingly rapid.

A pumping station belonging to the water company is located on South Branch a short distance below the mouth of Satterlee Run. In it there is a Dean pump and a boiler, also a well about fourteen feet in diameter and some thirty-seven feet deep from the top. The well is about forty feet from the South Branch and the water in the well stands about four feet above the water in the creek, although the bottom of the well is below the bed of the creek. The pump has its intake connected to the well but the outlet has been disconnected. This station has an appearance of not having been used for years and it is the reported purpose of the water company to dismantle the plant and use it elsewhere.

At Monroe borough the water company supplies about ten families with water and also furnishes water to other people living along the pipe line through whose property it was necessary to obtain right of way in constructing the line.

Just south of the borough line in the district known as South Towanda a ten inch lateral leads from the main pipe line up the adjacent hill side to a small storage reservoir having a capacity of approximately one hundred and fifty thousand gallons. This reservoir is merely an overflow from the city main; a twelve inch line extends from here into the borough and again connects with the main line.

In the borough an eight inch pipe leads from the main ten inch line up the hill through the middle of the town to a reservoir located about three-quarters of a mile west of the borough. This reservoir consists of concrete wall having been thrown across a slight ravine for a distance of about one hundred and fifty feet and an embankment perpendicular to it up one of the sides of the ravine for a distance of nine hundred feet thence an embankment at the upper end terminating at the opposite hillside. The upper part of the ravine is flat thus necessitating the long embankments and the embankment at the upper end. At one time a small stream flowed through the natural bed of this small valley, but it has been diverted to one side where a ditch paralleling the long embankment was dug to by-pass it around the reservoir. Paralleling the ditch on the opposite side is a public road. There is a small spillway at the upper end of this reservoir. Besides the main inlet pipe numerous springs on the hillside contribute to the supply. It is stated that the capacity is some fourteen million gallons. The water surface covers an area of five and three-eights acres. The hillside from which the springs emerge is well wooded and about two hundred feet away from the water's edge is the bed of an old State road which is now abandoned. There is a ditch paralleling this road between it and the water to carry off any surface pollutions which might enter the reservoir on this side. The whole area is enclosed by a wire fence excepting the side toward the public road which is protected by the embankment ranging from five feet to nine feet in height. The elevation of this reservoir above the lowest point is two hundred and fifty feet.

The water company reports that this reservoir has been used but once since it was finished in nineteen hundred and five, the time being August of that year. It appears that water was turned onto the borough on account of a break in the main pipe line but the muddy condition of the water received such condemnation from the citizens that it was decided not to use it and has not been supplied since. The company reports also that this location received the sanction of the old State Board of Health after a personal visit of the secretary.

The water company supplies most all of the population, there being one thousand and sixty-six taps. The section known as North Towanda also receives this water.

There has been little typhoid fever in Towanda. In nineteen hundred and five there were two cases and no deaths, in nineteen hundred and six there were six cases reported and three deaths, four of the six cases were found to have been brought into the borough from elsewhere. In nineteen hundred and seven, up to the middle of October, two cases and one death were reported.

The water company has submitted an application for permission to extend its water works and has submitted a plan of the reservoir last described situated on the Watkins farm in Towanda Township and desires the approval of the Commissioner of Health of this reservoir. It was finished in nineteen hundred and five and used for the first time in August of that year, but it was immediately shut off from the town supply and has not been used since.

The question of the purity of the water supplied to Towanda has been under discussion between the people and the water company for a number of years. As far back as nineteen hundred a report was made to the old State Board of Health in which it appears that at that time the water company stated it had in operation a seventy foot sand filter along the South Branch at the Eilenberger Springs, but evidence of its location or of its ever having been renewed or cleaned could not be obtained. This report also states that the water in the creek near the emergency intake was simply a shallow stagnant pool of water, its banks covered with decaying foliage, the surface of the water covered by an oily brick-red scum, floating debris and about one-half mile farther up the stream cattle were found feeding along its banks and wading in at will. The droppings from the cattle were to be seen not only on the banks but in the stream itself.

In nineteen hundred and one a representative of the old State Board of Health made an inspection of this water supply and reported the existence of the sand filter but believed that the water filtered through this medium would be objectionable. A considerable collection of black vegetable matter was seen under the intake of the spring basin which raised the question as to whether a small amount of water might not find its way into the pure supply from the creek through the plug emergency intake. The use of the waters of South Branch were condemned unless filtered consequently the emergency intake was condemned and its removal ordered. The report also stated that there would be no risk in supplementing the water received from other sources by the water furnished by the well located along South Branch, a short distance below Satterlee Run and suggested to the company the importance of having a chemical examination of each of its sources by thoroughly competent chemists approved by the State Board of Health at least twice every year and a bacteriological examination by a bacteriologist approved by the State Board at least once annually.

The Department is aware of the fact that during the fall of nineteen hundred and six a committee of the local Board of Health of the town council of Towanda went to the source of the water supply and found at the Eilenberger springs, a pipe carrying water from South Branch Creek into the pipe from Eilenberger springs so that almost as much water was being taken from the creek as from the spring. This committee found some farmhouses with their privy vaults and pig pens on the bank of the stream and smaller tributaries draining other farms and buildings. They also found a railroad paralleling this creek for a short distance above the intake from the creek. The local Board of Health at once disapproved of this condition and pointed out the fact to the water company that if a case of typhoid fever should occur at any of these farm houses above the intake, the water would be in great danger of contamination from the stools of the patients, and advised the people to use boiled water. The council refused to pay any more water rent until the creek water was eliminated from the supply. The water company paid no attention to the communication sent to them so that the matter was called to the attention of the Commissioner of Health, whereupon he called the attention of the water company to the existing conditions and advised that the creek source of supply be abandoned in order to obviate any possibility of a typhoid epidemic. In reply the water company forwarded a copy of a letter purported to have been written by the old State Board of Health approving the proposed supply from the South Branch and Satterlee Run and calling attention to the expediency of obtaining control of these watersheds to such an extent as to prevent the location thereon of dwellings or factories so situated as to pollute the water. This letter also states that the State Board of Health reserved the right to condemn this supply if at any time it finds it to have become polluted.

It appears that the contract between the water company and the borough states that if the Eilenberger springs should fail to afford an ample and constant supply of water to the public at all seasons, the supply of good water shall be made ample by taking the same from a source approved by the State Board of Health. It was this contract requirement which called for investigation in eighteen hundred and ninety-four of the proposed new supplies above mentioned.

In the report of this investigation it is stated that the watershed of the South Branch above the proposed intake was found to be almost totally uninhabited and free from contamination. The same being true of the proposed supply of Satterlee Run. In view of these sanitary conditions approval was probably given, but the present conditions are such as to cause the South Branch waters to be dangerous as a water supply.

In response to the information received complaining of the breach of the contract in supplying South Branch water, the Commissioner of Health on July third, nineteen hundred and seven, ordered an investigation made of the facts in connection with the water supply at that time.

The result of this investigation brought forth information that the reservoir covering at the Eilenberger springs was fastened with a lock, but was unlocked so that it could be opened at will by any one, and of the existence of an eight inch iron pipe leading from the creek bank to the main supply line. At this intake a small dam had been made by hoeing up part of the creek bed, so that the water above the dam was about eighteen inches deep. A piece of wire screen eighteen inches by twenty-four inches, having thirty meshes to the square inch, was held in place over the mouth of the intake by stones laid on the corners of the screen. The water was flowing into the pipe to the depth of five inches, it being laid on an easy grade. The creek was low and the water stood in pools covered with a greenish yellow scum. Cattle stood in these pools and defiled the water. It was reported that some twenty-one head of cattle stood in the creek just above the intake at one time.

In October, nineteen hundred and seven, one of the Department's engineers made an investigation of the existing conditions of this water supply and found among other things that this water company had built a new reservoir without a permit.

On the day of the Department's inspection in October, nineteen hundred and seven, the ground along the open jointed pipes leading directly from the Eilenberger springs was found to contain deposits of excreta. Although the land is within the enclosure hereinbefore described, it appears that some one had wilfully entered and committed a nuisance.

The water company contends that the quantity of water flowing from the Eilenberger springs is not sufficient for the supply to the borough, and that the combined supply from these springs and Satterlee Run is not sufficient in time of drought.

The auxiliary supply from Satterlee Run, if properly conserved, ought to be sufficient to go a long way towards supplying the extra demands of a dry season. A substantial intake dam should be constructed across the land whereby a greater amount of water, in fact the entire flow, could be taken into the pipe line. Much of this water is now allowed to run into waste. There is an ideal spot here for the erection of an impounding reservoir.

The South Branch water at the pumping station or at any point above or below the Eilenberger springs should not be used in its raw state for drinking purposes. The water company should properly filter the waters of this stream or abandon it as a source altogether.

The Department does not have a plan of the street mains in the town or a plan of the supply mains, intakes, watershed, etc., outlined for supply of water which the company furnishes to the public. Mere sketches have been submitted, but they are not reliable. A plan of the new reservoir has been submitted, but details are lacking.

There appears to be no good reason why the new reservoir water should be prejudicial to public health.

It has been determined that the use of a new reservoir will not be prejudicial to public health, and a permit is hereby and herein granted for its use and for the extension of the water pipes in the borough of Towanda, under the following conditions and stipulations:

FIRST: That the Eilenberger springs and the Satterlee Run supply shall be the the only sources with the exception of the waters naturally flowing into the new reservoir that the water company shall use. The South Branch waters are absolutely prohibited unless the water company shall install a modern water purification plant for the treatment and adequate purification of said South Branch Creek waters, plans to be first submitted to the Commissioner of Health and approved by him.

SECOND: The facilities by which the South Branch Creek waters are now directly or indirectly introduced into the water works system shall be entirely discontinued and cut off from the water works system.

THIRD: Satterlee Run watershed tributary to the point where the water company takes the flow of its system for its purpose shall be mapped showing the existence of all roads, and occupied estates thereon and the company shall file such map in the office of the Commissioner of Health. The Department of Health will co-operate with the water company in removing all menaces from the watershed and in maintaining sanitary conditions thereon, but the company shall visit every occupied estate monthly and report to the Commissioner of Health the sanitary condition. The company shall make arrangements to have reported to it promptly the existence of any infectious disease of water-borne character on the said watershed and such intelligence shall be communicated to the Commissioner of Health without delay.

FOURTH: The water company shall improve the intake dam across Satterlee Run and submit plans thereof to the Commissioner of Health for approval. The suggestions relative to the development of this source are commended to the careful consideration of the company.

On or before the first day of January, nineteen hundred and nine, the water company shall have prepared and have drawn to scale of sufficient size to be useful to the Deparment of Health a map of the borough showing the precise location of all water pipes, gates and drainage facilities. Also a map of the supply mains to the town with their grades and location of all valves, blow-offs and drainage facilities. Also cross sections and detail plans of the springs, collecting pipes, gates and valves and also the same relative to the new reservoir whose use is herein approved.

FIFTH: If at the time the water company submits these details herein called for, it will make a general application for permission to extend its distributing system, the Commissioner of Health will consider such proposition and may issue a permit therefor permitting the water company to make such extensions from time to time as the necessity may call for.

SIXTH: If at any time in the opinion of the Commissioner of Health the water works system or any part thereof has become a nuisance or menace or prejudicial to public health, then such remedial measures shall be adopted as he may advise or approve.

Harrisburg, Pa., October 6th, 1908.

WARREN, WARREN COUNTY.

Warren Water Company.

This application was made by the Warren Water Company, Warren Borough, Warren County, Pennsylvania, and is for permission to obtain an additional source of supply and to construct a filtration plant to purify said source and the water of the Morrison Run supply.

On March fifteenth one thousand nine hundred and seven the Commissioner of Health issued a permit to the said Warren Water Company to obtain an additional source of supply from wells to be driven on land owned by the company in the vicinity of the company's pumping station and among other conditions it was stipulated:

"The Morrison Run supply shall be either filtered or abandoned; but it may be kept as an emergency source and be used without filtration only in extreme cases. At such times, the local and State Department of Health shall be notified. Sanitary inspection of the watershed shall be made monthly by the company, who shall file reports thereof with the State Department of Health and take such precautionary measures as may be necessary to safeguard public health.

"Because, in case of great conflagration, it might be necessary to have resources to the Allegheny River water, the company may maintain an intake thereto, subject to conditions to be agreed upon by the borough council and the Water Company subject to the approval of the Commissoner of Health. Detailed plans of this intake and its connection shall be filed with the State Department.

"If at any time, in the opinion of the Commissioner of Health, the water supplied by the Warren Water Company to the borough is not suitable for drinking and culinary purposes, then such remedial measures shall be adopted as the Commissioner of Health may advise or suggest or approve, and weekly analyses of the water shall be made by the said company and reports thereof filed with the Department of Health, together with such other information relative to the operation of the plant as the State Department of Health may require."

These conditions have been complied with.

Soon after the introduction of the new well water into the system a marked deterioration in the quality of the ground water supply of the company was noticed. The water became harder and quantities of iron were found to be present. The company endeavored to ascertain the cause and to find a remedy. During this period frequent complaints were lodged with the Commissioner of Health by the public authorities and an entire new source of supply was demanded. The company early represented that it would abandon the ground water supply or install a purification plant to render the water and the Morrison Run supply satisfactory to the consumers. The question of appraisement and purchase by the municipality of the water works plant was taken up by the citizens and the borough council, and upon inquiry by the Commissioner of Health it was ascertained that the company would defer submitting plans for an improved water supply until it was determined whether the borough would purchase the plant. It appears the company is now prepared to proceed immediately with the erection of the purification plant and plans are submitted therefor.

The company purposes to entirely abandon its present pumping plant and driven wells system as soon as the new supply is installed.

It is proposed to erect a new filter plant and puming station on the north bank of the Allegheny River in Glade Township at the bend in the river immediately below the Glade Run bridge over the river. The ten inch gravity supply main from Morrison Run reservoir is laid across the bed of the river at this point and thence extends in and along Pennsylvania Avenue to Warren. The borough line may be two thousand feet down stream from the river bridge. Here in the township is a small village called Glade Run and the tannery said to be owned by the Elk Tanning Company located on the banks of the run. Below in the borough there are several industrial plants including refineries, acid and chemical works. At the bridge there is a hotel and easterly along a highway, there are a few dwellings. The land becomes rapidly precipitous from the river bank up stream from the bridge and the slopes are unoccupied. A branch of the Pennsylvania Railroad is laid along the river bank and between this railroad and Pennsylvania avenue immediately below the said bridge, is a triangular tract of land less than one acre in area, upon which the company plans to build the filters and pump house. There is a strip of land between the railroad and the river about fifty feet wide, on which there are three dwellings and a barn. These properties are not included in the company's contemplated purchase. Between the tannery and the said triangular tract, there is a plot of ground about two hundred feet wide now occupied by a private residence.

This site has been selected by the company for three principal reasons: first, it is adjacent to the Morrison Run supply main which supply it to be filtered: second, the ground is elevated with the exception of one corner, above the highest flood ever recorded; and third, it is opposite deep water in the river.

The Allegheny river above Warren is sparsely populated. The stream and its tributaries are subjected to a minimum pollution. The waters are soft and easily purified and afford a never failing source. It is believed that under the law providing for the preservation of the purity of the waters of the State for the protection of the public health, that the Allegheny river will never be more polluted than at the present time, and that the few scattered sources of contamination now existing on the watershed both in Pennsylvania and in the state of New York, will in the near future be entirely eliminated, and consequently the company represent that its plans for a permanent source of pure and wholesome supply for Warren are worthy of approval.

It appears that north of the Glade Run bridge there are two islands of considerable size in the river. One of them next the north shore is long and narrow and at low water this channel is said to go dry or nearly so. The main channel between the two islands during low water which may cover a protracted period, is about eighteen inches deep, so it is reported. The current is rapid over these shoals. The bed of the river is gravel and small boulders and rather stable.

Between the southerly island called Rogers Island, and the river bank is the mouth of Dutchman Run, into which nearby, Morrison Run empties. The main line of the Philadelphia and Erie Railroad extends up the valley of Dutchman Run and about two miles from the river in Mead township there is a station and village on the railroad and the run called Stoneham, where there are tanneries, the drainage of which in a pronounced degree pollutes the stream. The dark color imparted to the water peculiar to tannery wastes, is discernible at the mouth of the run and

it follows the south bank of the river diminishing in color but visible at the Glade Run bridge. The bend in the river at this point to the north down stream produces a current towards the south bank so that under existing conditions, it is physically impossible for the Dutchman Run water to reach the north bank at the bridge and it is at this point one hundred and forty feet below the bridge and about one hundred feet out from the shore in a natural depression assuring a depth of five feet at extreme low water that the company purposes to establish its intake. The river at this point is said to be fully seven hundred feet wide.

The power plant is to be installed in a brick building comprising a boiler room in which is to be erected two water tube boilers each two hundred horse power, an engine house, a coagulating room, laboratory and shop. The main floor is to be laid two feet above the highest recorded flood level of eighteen and fifty-eight hundredths above low water.

The eighteen inch suction pipe from the river is to be connected directly to duplicate pumping engines each three million gallons capacity per twenty-four hours. The raw water is to be raised to the settling tank, a steel structure fifty feet in diameter and twenty feet high, set in the ground, its flow line designed to be five feet above the surface of the filters or thirty-two feet above low water. The coagulant solution is to be introduced into the raw water pipe between the pumps and the settling tank by approved apparatus. There is room for an additional tank when it becomes necessary. One tank will give a subsidence of between two and three hours under present rates of consumption and this is thought to be sufficient for local conditions. Morrison Run water is to be discharged into the sixteen inch force main leading from the raw water pumps to the settling tank. During rainy seasons, and for a number of months of the year the flow of Morrison Run will be sufficient to furnish all of the water to the plant. It will be only at such times as this supply is insufficient that the river water is to be used.

The raw water will be delivered into the tank at the top over an inlet trough and passing under a submerged baffle board across the middle of the tank it will leave by means of a skimming trough at the opposite side and thence flow to the filters. By an arrangement of piping the raw water will be by-passed directly to the filters whenever the settling tank is cleaned out. A twelve inch sewer pipe, cast iron, will take the drainage to the river bank and this sewer will also drain all wash water from the filters.

The filters and filtered water basins beneath are to be housed in a separate structure. The basins are to be laid wholly in excavation but the filters will be above ground. The construction is to be reinforced concrete and over all exposed to sight the filters will occupy a space about fifty feet square. They will support a roof, the walls of which will come to within about five feet of the sides of the filter. This outside space is to be utilized for the depositing of sand from the filters.

There are to be six filter units arranged in parallel rows of three with the operating platform and pipe gallery between. Each filter unit is to have an area of one hundred and seventy-six square feet and to be capable of filtering five hundred thousand gallons of water per twenty-four hours.

There is a twenty inch raw water pipe from the settling tank to the filter off of which an eight inch pipe is taken to each filter unit terminating in an inlet chamber extending across the entire width of the end of the unit. The heighth of water over the surface of the sand is regulated by butterfly valves and there is a four inch overflow pipe set two inches above the water line which is three feet four inches above the sand surface. The depth of sand is to be thirty inches supported by ten inches of gravel resting on a steel false bottom into which the strainers are screwed and under which there is a free passage way for the filtered water of about twenty-four inches in depth. From this horizontal collecting chamber, the filtered water is piped at the rate controller in the operating gallery and thence it goes to the filtered water basin below. The total capacity of the basin is one hundred thousand gallons.

A centrifugal pump, capacity two thousand gallons per minute is provided for washing. It will deliver filtered water through a twelve inch pipe with eight branch into the bottom of each unit and upward to two steel collecting troughs whose edges are to be set twenty-one inches above the sand surface. They will discharge into the vertical inlet chamber and thence to the sewer. Pipe arrangements are provided for the wasting of the first filtered water.

All valves have stems extending to above the operating platform. This platform is made of concrete construction water tight so that no possibility of contamination of the filtered water below is afforded.

A connection with the supply main to the town will be made so that wash water can be used under pressure in case the wash water pump should be out of repair.

The filtered water is to be raised into the pipe system of the town by three pumping engines. One of them is to be a three million Worthington horizontal triple expansion engine. The second a two million Worthington compound, and the third, is to be a one million, five hundred thousand triple expansion engine. The latter is to be used principally to pump water into the reservoir on the hill. The other pumps will be placed on the town service and pump water directly into the distribution system. Paralleling the present ten inch main to the borough is to be laid a new twelve inch force main part way and a ten inch main the balance of the distance to the center of the town and the pipe to the reservoir. By this

arrangement it will be possible to pump filtered water directly into the distributing reservoir on the hill without passing it through the distributing system and this is the plan of operation intended.

In submitting these plans for approval the company represent that the expense involved in the erection of the plant will be large and more than should be incurred, but the investment is considered a permanent one and so the best design is submitted. The establishment of a laboratory is made a part of the plan because of the intention of operating the filters in the most efficient manner possible. While the plant is to be operated continuously and the supply from Morrison Run or from the river is much more suitable in its raw state to be furnished to the public than many of the domestic supplies in Pennsylvania, nevertheless the petitioners request that the Commissioner of Health remove from the watershed of the Allegheny river above the intake, all sources of sewage pollution at as early a date as may be found practicable.

There is a saw mill on Rogers Island. There is a club house on an island further up stream besides the hotel and adjacent dwellings which require to be inspected and looked after. This is clearly within the province of the State Department of Health and will be attended to.

Should conditions change before the tannery wastes now discharged into Dutchman Run are required to be treated whereby the wastes might reach the north bank of the river passing over the proposed new intake and interfere to any appreciable extent with the efficiency of the filter plant, it does not appear that a remedy would not be at hand as easy of adoption then as it would be at this time. The expense of providing an intake further up stream will be very considerable and it need not be undertaken until there is sufficient warrant for the expenditures.

It has been determined that the new source of supply and the plans therefor are not prejudicial to public health and the same is hereby and herein approved and a permit granted therefor under the following conditions and stipulations:

FIRST. That when the new works shall have been established the old pump house and driven well supply shall be absolutely abandoned.

SECOND: Weekly reports of the operation of the water works system, particularly of the purification plant shall be made to the State Department of Health on blank forms satisfactory to the Commissioner of Health. If at any time, in said Commissioner's opinion the water works system or any part thereof, has become defective or outgrown or insufficient, or the water furnished thereby prejudicial to public health, then such remedial measures shall be adopted by the Company as the Commissioner of Health may approve or advise.

THIRD: Because Morrison Run is now the major supply and in view of the stipulation in the decree of the Commissioner of Health of the Warren Water Company relative to Morrison Run supply under date of March fifteenth, one thousand nine hundred and seven, wherein it is stipulated that such supply shall either be filtered or abandoned, it is herein specially stipulated that the purification plant herein approved shall be erected and put into commission on or before eighteen months from the date of this permit. The water company will notify the Commissioner of Health when the new plant is put into commission. The company shall make a sanitary inspection of the Morrison Run watershed in the spring and the fall of each year and file reports thereof with the State Department of Health and take such precautionary measures on the watershed as may be necessary to safeguard public health.

FOURTH: This permit is issued with the understanding and stipulation that the filter plant is to be operated under skilled management and that the laboratory is to be used regularly in connection with such operation.

FIFTH: No sewage from the pump house or filter plant shall be discharged either directly or indirectly into the river. The company shall make monthly inspections of the three properties on the river bank opposite the purification plant and of the hotel and dwellings in the vicinity and of the saw mill on Rogers Island and dwellings in that vicinity and make reports thereof to the Commissioner of Health. It is the purpose of the State Department of Health to require a proper disposal of sewage at all occupied estates above the proposed water works intake.

Harrisburg, Pa., June 29, 1908.

WATERFORD BOROUGH, ERIE COUNTY.

Waterford Water Company.

This application was made by the Waterford Water Company of Waterford borough, Erie county, and is for permission to obtain an additional source of supply and to extend water works to supply water to the public in said borough.

Waterford borough is in Waterford township in the central part of Erie county, fifteen miles south of Erie city. The municipal territory is rectangular and contains a little less than one square mile. At the southwest corner are the shores of the LeBoeuf Lake, a body of water of considerable size, containing approximately over half as much land as lies within the borough. Leading into this lake is Beaver Run which passes by and through the western part of the village, having its source in the western portion of Waterford township about five miles above the lake.

The main feeder, however, is LeBoeuf Creek which heads in Summit township near Erie city and with its tributaries drain about fifty square miles. Below the lake this creek has a length of about two miles to the point where it empties into French Creek. Above the lake its course is due eastward away from the borough for a mile, whence it turns to the north. The Philadelphia and Erie Railroad from Erie city passes down the valley of this creek, Waterford station on the railroad being in the township one mile east of the borough.

Waterford borough was incorporated in eighteen hundred and thirty-three. Its population at that time was about four hundred. Now it is about eight hundred. The country round about is wholly agricultural and the village is residential. Besides the stores, there is a carriage shop and blacksmith and a grist mill. In provincial times Fort LeBoeuf was located in this vicinity and the site was early selected for a town. There are no immediate prospects of any great change in the size or character of the present borough.

There are no public sewers and but one private sewer. This leads from the Park Hotel to a swamp in the northwest part of the borough where it empties. Such disposal has not caused any complaint so far as is known.

Domestic wastes from dwellings is discharged into cesspools and privies. It is reported that the number of cesspools does not exceed a half dozen. The sub-soil and underlying earth is of a clayey, retentive nature. The water supply is generally obtained from dug wells walled up with loose stone and located on individual property. The surface of the ground within the borough is generally quite even, ascending gradually from the lake and the creek to the northern part of the borough where it has an elevation of about sixty feet above the lands along the creek. The danger from surface contamination, therefore, is minimized as is that from sub-soil pollution. The health of the inhabitants generally is excellent. The surroundings of private estates are kept in a sanitary condition.

The borough council by ordinance passed May twenty-second, nineteen hundred and six, granted to Charles Himrod and his assigns the right to construct and maintain and operate a system of water works for the purpose of furnishing fire protection and for other purposes.

It appears that Mr. Himrod originated a scheme to obtain a gravity spring water supply for his private residence in Waterford. The spring was so situated that the pipe from it would necessarily pass through several of the village streets on the way to the Himrod mansion. Owners of abutting estates along this line desired the privilege of tapping the pipe and, Mr. Himrod consenting, the ordinance above cited was enacted by the borough council. The system was installed in nineteen hundred and six and water was furnished for the first time in September of that year. It is represented that the applicant did not then know of the law requiring State approval of plans and sources of public water supply.

The Waterford Water Company of Erie county was chartered on September thirteenth, nineteen hundred and seven to supply water to the public in said borough, such supply to be obtained from springs on outlets fifty-six, fifty-seven and fifty-eight in the borough, leased from D. W. Hunt, and from the "Woods" spring and other springs purchased from William Taylor and wife, located on the Taylor farm, being part of tract "E" in Waterford township.

The plant as it now exists comprises a collecting and storage reservoir at the springs on the hill in the northeastern part of the borough and the gravity pipe lines in the borough streets.

A spring formerly gushed forth from a gravel strata underlying several feet of clay in a slight depression. The petitioners excavated the surface earth here, exposing several other springs, and enclosed them all in an earth and clay embankment ninety feet long, seventy feet wide and six feet high. The capacity of this reservoir to a depth of four feet is two hundred thousand gallons. The territory from which the water is yielded is to the north beyond the borough. It is rolling farm land. Around the reservoir has been erected a tight board fence about six feet high and guarded on top by a barbed wire. A pipe leads from the bottom of the basin for drainage purposes. The measured flow of the springs in the reservoir is stated to be twenty-four thousand gallons per twenty-four hours. There are several small springs about six hundred feet north of this reservoir and on higher ground which may be utilized when required.
